ABSTRACT. Riemann stated his hypothesis as a fixed-set statement, that the roots of $\zeta(t)$ are real. This paper proves, in core Lean 4 with no library and no axiom declared, what existence decides about that statement, its seat, and that its value lies beyond existence's reach, and then proves the part of the value that is reachable. Part I proves the seat, with the Root Axiom as the only posit: the fixed locus of conjugation on the quaternions is the scalar line, the chart of the critical line embeds onto it, and the three readings meet at one point; the value on the zeros is one bit, unreachable from existence, since $(RA \rightarrow L) \leftrightarrow L$. Part II proves every reading of that bit reached from existence, time, and monism one proposition with the hypothesis at its apex, given the imported inputs, and shows that the hypothesis posits no object while its denial posits one, a finite witness never produced. Part III divides the hypothesis at any height T into a Real part, every zero up to T on the line, and a Unicorn part, no off-line zero above T ; proves the split exact, the fused statement only as strong as its open part, and the hypothesis equivalent to the statement that the off-line zeros are unicorns; and carries the Real part from a finite certificate into ZFC along the RA-RAM bridge, every step holding with the axiom replaced by a bare computation arrow. So the Real part is proved, for ζ to height 3×10^{12} on the certificate of Platt and Trudgian. The Unicorn part is named and set apart, not proved. Parts I and II are then read at the Unicorn part: it is closed to derivation, from existence, from any class of frames, and from any reading of an even register at its seat, at theorem grade and in perpetuity; its aperture is located, typed supply-only, one bit wide, and uncrossed; and the register is silent on the supply side, both orientations equally refused to every reading, which is why the title says the Real part and not the hypothesis. Three bits close the arc. One bit divides: the hypothesis is exactly its Real part and its Unicorn part, at every height, by theorem. One bit is proved: the Real part, to that height, by certificate through the schema. One bit is refused at theorem grade: the Unicorn part is closed to every derivation from inside the register; its aperture is structure, one bit wide and uncrossed; the supply side is silence, by theorem at the register. With the three bits in hand the proof is complete on the register side: everything a register can prove about the hypothesis is proved, and the remainder is proved to be beyond derivation, with its aperture typed and its supply side silent. The hypothesis is not claimed proved; what is claimed is that no further derivation is owed to it. Nothing is left to derive. The aperture is structure. The supply side is silence.

INTRODUCTION

Riemann stated his hypothesis as a fixed-set statement: the roots of $\zeta(t)$ are real [Riemann 1859]. A prior paper of this program [Islam 2026e] restored that statement to $Z \subset \text{Fix}(\tau)$ with $\tau(s) = 1 - \bar{s}$, defended the restoration against the literature, and proved in core Lean 4 the structural arc of the restored hypothesis on

an abstract frame $X = (S, \tau, Z)$: the locus, the odd offset, the orientation blindness of every even reading, the one-bit freedom, the halting carrier, and the crossing. It also proved what the arc is not. Every structural clause holds on a frame whose zeros lie off the line (its Theorem 11); the only input that closes the crossing on the frame of ξ is a term of $L(X_\xi)$ itself (its Theorem 12); no theorem whose hypotheses are only structural decides L (its Theorem 14). The value, $\forall \rho \in Z_\xi, \tau\rho = \rho$, was recorded as the one open input, entered at a recorded row and never derived. We call that row the witness row and the point at which a value enters a file from outside it the aperture; both terms are the prior paper's and are used here in its sense. Two objects carry the name Riemann Hypothesis in what follows and are written with two tokens that are never joined: $\text{RH}_{\text{formal}}$, the seat, the restored statement read as the fixed locus of its binding involution, which this paper proves with existence as the only posit; and $L(X_\xi)$, the value, the statement that every zero lies on that locus, which this paper proves existence does not reach. Part I names the first and excepts the second, and the exception is Theorem I. "From existence alone" has one meaning in this paper: existence is the only posit, and nothing else is assumed. It does not mean that the seat is derived from existence. The seat holds by the definition of the Ground and consumes no premise (recursion_is_constant); existence is consumed where it has content, at presence (Theorem D), at the closure of the interaction reading (RAF-C1), and at the ledger, where every adjudication of any proposition is a deed and therefore an instance of existence and of nothing else (adjudicating_anything_instances_existence). That last theorem is what existence contributes that no other true premise does.

Notation and the objects named. The Root Axiom, written RA, is the posit $\forall x \in U, \Delta E(x) > 0$ on a universe U with a differential $\Delta E : U \rightarrow \mathbb{Z}$: to exist is to actuate. Existence and RA are one proposition; the paper writes RA in formulas and existence in prose. RA has two published formal readings [Islam 2026j]: the interaction reading, RAF, which reads the axiom as the criterion for systems being related, registration carrying positive mutual information and an interaction domain being closed under it; and the grounding reading, RAM, which reads the axiom as the criterion for a proposition being determinate, its imprint in the fixed locus of a binding involution. A frame is $X = (S, \tau, Z)$, a carrier S with an involution τ and a distinguished subset Z ; its line property is $L(X) :\Leftrightarrow \forall s \in Z, \tau s = s$. On the frame of ξ , with $Z = Z_\xi$ the zeros and $\tau(s) = 1 - \bar{s}$, $L(X_\xi)$ is the restored hypothesis, and it is called the value. The carrier the paper builds is the integer quaternions $\mathbb{H}_\mathbb{Z}$ with conjugation σ as its binding involution; the seat is the fixed locus $\text{Fix}(\sigma)$, a seat point is a point of it, and $\text{RH}_{\text{formal}}$ is the seat read as a proposition, that every point of $\text{Fix}(\sigma)$ is fixed by σ . A register is one of three readings of the seat, the axiom register RA, the formal register RAM, and the object register RH, and the three form the register diagram. The witness row is the recorded row at which the value is entered; the aperture is the point at which a value enters a file from outside it; the world row is the witness row read in the world register; the sign is the value $\forall \rho \in Z_\xi, \tau\rho = \rho$, the one bit. ΔM counts the mathematics authored and is zero throughout. Every other symbol is defined where it first appears.

Two things in that record are external to its file, and this paper brings them inside. First, the prior proof's live face takes its "witnessed" flag from the command line: that a supplier is present is asserted from outside, and the kernel is told rather than shown that a reader stands at the aperture. Second, three separations are left standing: between the axiom under which a reader acts, the formal ground on which the locus was fixed, and the Riemann object read as the fixed locus of its binding involution. These are separations of description, produced by reading one seat in three registers, and not gaps in the mathematics. The prior proof could not close them because an axiom is not a structural clause and the prior proof had none.

The Root Axiom is that axiom. Formally it is a universe U with a differential $\Delta E : U \rightarrow \mathbb{Z}$ and the statement $\forall x \in U, \Delta E(x) > 0$; its published form, its physical warrant, and its two formal readings are in [Islam 2026a, Islam 2026j]. The interaction reading (RAF in [Islam 2026j]) says what it is for systems to be related: an interaction domain is closed under registration, and no agent acts on a domain from outside it. The grounding reading (RAM in [Islam 2026j]) says what it is for a proposition to be determinate: its formal being is its imprint in the fixed locus of the binding involution, read across the aperture, with $\text{Fix}(\sigma) = \mathbb{R}$ as the seat. The interaction reading reaches no mathematical object, since mathematical objects do not change state; every proposition routes to the grounding reading [Islam 2026j, Islam 2026i]. That reach law is the axiom's own, and this paper proves its Riemann instance rather than assuming it.

Two objects are new here. The first is the constructed witness: the axiom built in the kernel as a structure in Prop with four fields, the only proof object the closure is allowed to consume, and the eliminator that runs from it alone, $\text{RA} \rightarrow \text{RA} \rightarrow \text{RAM} \rightarrow \text{RH}_{\text{formal}}$: the witness's last field, a function from the orientation

and the formal Ground to the formal self, applied once, with every leg of the chain a definitional equality. The second is the category-gap eliminator itself: the three separations exhibited as the three legs of a cone over the register diagram, each leg an identity, so that the separations close at zero cost and the closing is computed rather than asserted. Everything else the paper uses is published: the frame and the structural arc [Islam 2026e], the one-bit result [Islam 2026b], the odd-supply separation and the one-cut hypothesis across twenty-three rows [Islam 2026c], the formal-alone theory of registration, price, and crossing [Islam 2026d], and the axiom's declaration [Islam 2026j].

This paper constructs the axiom and proves the following about it in relation to the hypothesis. The seat: conjugation on the quaternion carrier fixes exactly the scalar line, the Return of the parse triad lands on it, and the axiom's seat point, the formal seat point, and the named seat point are the three legs of an identity cone over the register diagram, each leg rfl , the apex unique per orientation of the triad (Theorems A, B, C). The embedding: the prior proof's lattice stage embeds equivariantly and injectively into the carrier, $\sigma\varphi = \varphi\tau$, and φ carries the line onto the scalar line at every resolution (Theorem C'). The aperture: for a present reader who supplies a bit the row is never interior; it is sealed or refused by the bit alone, and a reader who registers a bit is inside the axiom's domain, never an exterior witness (Theorem D). The exact strength of the rule: in every context in which the axiom holds, $(\text{RA} \rightarrow L(X)) \leftrightarrow L(X)$, and the axiom decides L on no frame, the two-point frame carrying the axiom and failing L (Theorems E, F). Every theorem is checked by the Lean kernel; every finite claim is re-executed by a compiled Fortran program that shares no code with the kernel, and both records are printed whole.

Part I names the register and the residue. At the axiom a closure can carry no mass: a closure between the axiom and its formal reading that added a premise would be a second axiom, which the axiom's own root-premise theorem forbids [Islam 2026a]. The eliminator that closes the category gaps is therefore massless by necessity and not by weakness, and this paper computes the masslessness rather than asserting it: the three legs of the cone are definitional identities. "In toto at the apex" has one definition and it is used in no other sense: every clause of the hypothesis that is not its value on the zeros. "The sign" names one object throughout: the value $\forall \rho \in Z_\zeta, \tau\rho = \rho$, the orientation of assent on the world row, the one bit the prior proof records at the witness row. "Everything but the sign" is the same set named by its complement. What the kernel returns, given the axiom, is exactly that set, and the sign is proven to be exactly what the axiom does not reach.

The value, its readings, and its address

That bound is correct, and it is also where the ordinary reader's second question begins. If one bit is owed, what object would carry it? The candidates proposed in the literature, an Euler-product class, a self-adjoint operator, a positivity criterion, a monotone flow, are different-looking objects. A reader who pursues them in turn meets what looks like a regress: each candidate, once formalized, turns out to need a further ingredient, and each further ingredient looks like a new missing piece. The barrier this paper addresses is that appearance of regress, and it is structural rather than computational.

The barrier has three layers. The first is register confusion. A timeless formal reading of the hypothesis deletes the index along which the zeros are counted, and a reading that deletes its own index cannot distinguish a claim from its negation. The kernel exhibits this as sign-blindness; Part I's `recursion_is_sign_blind` is its receipt. A verdict issued from that register is a verdict of an amputated instrument, not a finding about the zeros.

The second layer is type mismatch. The natural "arrow" a physical reading supplies is a sign, one Boolean. The hypothesis asks for a vanishing: that the off-line offset δ of every zero is zero. A sign does not force a vanishing. A supplied orientation picks which member of a mirror pair $(\frac{1}{2} + \delta, \frac{1}{2} - \delta)$ comes first and leaves δ untouched. The barrier dissolves only when the vanishing is rewritten as a family of signs, one per step of an index, and Li's criterion [Li 1997] is exactly that rewriting.

The third layer is the uniformity trap. Every instrument that closes a category gap at the apex is massless by necessity, because a closure between existence and its reading that authored mathematics would be a derivation of the root from below [Islam 2026a]. A massless instrument chooses its objects without reading which L-function it serves. Such an instrument is uniform across the family, and a uniform instrument forces positivity on every member, including members whose zeros leave the line. The Eisenstein L-function $\zeta(s)\zeta(s - k + 1)$ has an Euler product and a functional equation and zeros off its center line [Iwaniec and

Kowalski 2004]. It is not primitive; after the shift that centers its functional equation at $\frac{1}{2}$, its zeros lie off that center, and Bombieri-Lagarias then gives a negative coefficient. In the kernel the control enters abstractly, as a family member with a negative coefficient, and it kills every uniform instrument. The bit must therefore be carried by an object that reads ζ specifically.

The domain of validity of the standard approach is precisely mapped by these three layers. Classical analytic number theory works inside one register, the timeless one, and it has reached the classical consequences of positivity on the Euler product: nonvanishing for $\text{Re } s > 1$, and through Mertens' positivity, nonvanishing on $\text{Re } s = 1$ [Hadamard 1896; de la Vallée Poussin 1896; Mertens 1898]. Beyond that line the Euler product diverges and positive energies have nothing to act on. The strip $\frac{1}{2} < \text{Re } s < 1$ is where the timeless register stops and where a reading indexed by time must take over.

Part II does not cross that strip; Part III crosses it only where computation has certified the zeros, up to a finite height. What Part II does is prove that every road into the strip reached from existence, time, and monism is the same road. The regress is shown to be an artifact of reading one seat in several registers, and the category-gap eliminator of Part I, applied to those registers, collapses it to one gap. The gap is then pinned, typed, and left at the witness row where Part I placed it.

The division of the value

Part III divides the hypothesis. It does not reopen the value that Parts I and II locate, and nothing in it contradicts Theorem I. One part is reachable, and it is proved here along a road built from the Root Axiom through the RA-RAM bridge, the RAM strata, and ZFC. The other part is the region where the denial's object would have to live, and it is named for what it is and set apart.

Three bits, and what is claimed. The whole paper is three bits. One bit divides: the hypothesis is exactly its Real part and its Unicorn part, at every height, by theorem (III.11). One bit is proved: the Real part, to 3×10^{12} , by certificate through the schema (III.34 to III.36). One bit is refused at theorem grade: the Unicorn part is closed to derivation from existence, from any class of frames, and from any reading of an even register (III.45 to III.48); its aperture is located, typed supply-only, one bit wide, and uncrossed (III.46); and the register is silent on the supply side, both orientations equally refused (III.49). The Unicorn part is unproved, and the reason is neither a want of effort nor a want of ability: it is a theorem, and the theorem says which routes are closed, which is all of them but the aperture, and says nothing of the aperture but its width. With the three bits in hand the proof is complete on the register side. Everything a register can prove about the hypothesis is proved; the remainder is proved to be beyond derivation, its aperture typed, its supply side silent. The hypothesis is not claimed proved. What is claimed is stronger than an open problem and weaker than a theorem: no further derivation is owed to the Riemann Hypothesis. The three bits are one term in the kernel (`rh_register_proof_complete`). Nothing is left to derive. The aperture is structure. The supply side is silence.

RELATED WORK

Only the positions that bear on the apex are reviewed; the analytic literature of the restored formulation is reviewed in [Islam 2026e].

The original statement and its chart. Riemann [Riemann 1859], Siegel [Siegel 1932], and Edwards [Edwards 1974] give the fixed-line statement and its history; Titchmarsh [Titchmarsh 1986] and Conrey [Conrey 2003] state the canonical chart form, real part one half. The prior paper's Proposition V1 makes the address a chart and the fixed line intrinsic. This paper takes the fixed line one register deeper: the fixed line of a binding involution is the seat on every carrier that has one, and the two carriers in play, the lattice stage under τ and the quaternions under σ , are joined by an explicit equivariant map.

Symmetry without the Euler product. Davenport and Heilbronn [Davenport and Heilbronn 1936] and Bombieri and Hejhal [Bombieri and Hejhal 1995] exhibit series with the functional equation and zeros off the line. In the prior proof these are the off-line frames on which every structural clause holds. Here they carry one thing more: the Root Axiom holds on them too (Theorem F). That is the whole reason the axiom cannot decide the value.

The Euler product as key. Selberg [Selberg 1992] and Conrey and Ghosh [Conrey and Ghosh 1993] name the Euler product as the organizing axiom of the class for which the hypothesis is conjectured; Weil [Weil 1948] and Deligne [Deligne 1974] prove the analogue where the Euler product runs over a finite ge-

ometry. Part I leaves the key where the prior proof left it, on the world row, and shows that the apex closes without it; Part III turns the key by computation up to a certified height, and no further.

The spectral road. Berry and Keating [Berry and Keating 1999] and Connes [Connes 1999] seek an operator whose spectrum is the zero set. An operator is a world-row construction; the seat on which its spectrum would have to lie is fixed before any operator is built, and that ordering, orientation after construction, is a theorem of the twenty-three-row study [Islam 2026c].

The program's own prior results. The one-bit result [Islam 2026b] located the hypothesis at exactly one bit from its structural arc. The twenty-three-row study [Islam 2026c] typed every proved method-class barrier as an evenness statement and every open row as missing exactly one orientation bit at its decision seat, and stated the one-cut hypothesis: that each such row is closed by one cut, the supply of that bit. The formal-alone theory [Islam 2026d] fixed registration, price, crossing, and cost as the four faces of a supplied bit. The earlier termination and case-closed papers [Islam 2026h, Islam 2026g] recorded the hypothesis's standing under the program's cascade before the restored form was proved. The present paper is the apex of that sequence: Part I places the Riemann row's owed bit against the one seat under every name and proves that the axiom reaches everything but that bit, and Part III divides that bit and proves its Real part.

The axiom's formal readings. The declaration of the formal Root Axiom [Islam 2026j] states RAF-1 and RAF-2, the bridge to Landauer, and the consequences C1 to C3, and states RAM as the imprint law with $\text{Fix}(\sigma) = \mathbb{R}$. Its engine records the constraint this paper obeys: the interaction reading reaches no mathematical object and routes every proposition to the grounding reading [Islam 2026i]. Cantor's diagonal theorem, which Lawvere's fixed-point theorem generalizes [Lawvere 1969], carries C2 unconditionally.

Category-theoretic frame. Cones, apexes, and limits over a diagram are used in their elementary form, a discrete diagram on three objects in the groupoid of definitional equalities [Mac Lane 1998]. The frame is chosen because a category gap is, in that setting, exactly a missing leg, and its elimination is exactly an identity leg.

The price of the act. Landauer [Landauer 1961] bounds the dissipation of registering one bit; Bérut and coauthors [Bérut et al. 2012] measure it. The prior proof prices the spent bit at $k_B T \ln 2$; here the price is the bridge of the interaction reading and it exports without constituting.

The gap. No work in this literature states the axiom under which the supplier acts, so the presence of a supplier remains a flag; and none treats the three separations between axiom, formal ground, and object as what they are, separations of description rather than of mathematics. Both are supplied here.

The readings of the value

Li [1997] proved that the hypothesis holds iff $\lambda_n \geq 0$ for every $n \geq 1$, where $\lambda_n = \sum_p [1 - (1 - 1/p)^n]$. Bombieri and Lagarias [1999] generalized the criterion to multisets of zeros and showed that an off-line zero drives some λ_n negative. Their theorem is the analytic content behind this paper's reading of Li's coefficients as modes of a time evolution.

Weil [1952] gave the explicit formula and the positivity criterion that bears his name; in it the primes enter with a negative sign against an archimedean term. Deligne [1974] proved the function-field analogue, where the decisive ingredient is a positivity supplied by geometry. Selberg [1992] and Conrey and Ghosh [1993] name the Euler product with primitivity and the Ramanujan bound as the organizing axioms of the class for which the hypothesis is conjectured.

De Bruijn [1950] introduced the heat flow $H_t(z) = \int e^{tu^2} \Phi(u) \cos(zu) du$ and proved the strip-narrowing theorem. Newman [1976] defined the constant Λ and conjectured $\Lambda \geq 0$. Rodgers and Tao [2020] proved it. The Polymath project [Polymath 2019] proved $\Lambda \leq 0.22$. The hypothesis is therefore equivalent to $\Lambda = 0$.

Beyond the spectral road above, Stone [1932] proved that a strongly continuous one-parameter unitary group has a self-adjoint generator; the section on the witness rebuilt uses it to pass from a unitary evolution to its generator. Julia [1990] and Bost and Connes [1995] realized ζ as a partition function over the primes.

Perelman [2002; 2003a; 2003b] proved the Poincaré conjecture through Ricci flow, with the monotonicity of the $\mathcal{W}$ -entropy as the transport that carries control along the flow. De Branges proposed a positivity condition intended to prove the hypothesis; Conrey and Li [2000] showed it fails.

Littlewood [1914] and Skewes [1933], Haselgrove [1958], and Odlyzko and te Riele [1985] are the standing warnings against inference from finite confirmation.

The approaches reviewed here are each developed around their own object, and each is read in this paper as one register's version of the missing piece. the section on halted uniduction proves that these objects, in the forms reached here, are one proposition.

METHODS

Two independent checkers

Every theorem of this paper is checked by core Lean 4, version 4.19.0, no library, no axiom declared by the file, no sorry; the kernel's own `propext` and `Quot.sound` enter only through integer arithmetic and are listed per theorem, every dependency set printed by the kernel and reproduced in Appendix C. The file, `RH_At_The_Apex.lean`, is printed whole in Appendix B with its SHA-256 digest, and it is self-contained: the prior proof's Theorems 1, 4 through 9, 12, and 15 are re-proved inside it on the same abstract frame and the same lattice stage, so that the apex layer rests on nothing it does not carry.

The finite content of the file, itemized below, is re-executed by a second checker that shares no code, no logic, and no toolchain with the first: a Fortran 2008 program, `RH_At_The_Apex_Twin.f90`, compiled with `gfortran`, printed whole in Appendix D with its run log in Appendix E. The twin enumerates rather than proves. It checks conjugation against every integer quaternion in a lattice ball, the Return and its six orderings, the three identities and the cone census over the whole ball, the embedding's equivariance, image clause, and injectivity at seven resolutions on a lattice window, the wall over every one of the 2^{13} readouts of the seat's window, the two wholly odd maps and their calibration, the aperture on a twelve-point domain, the truth table of the rule and the two-point counter-model, the ledger, the refusal constant, the price, the closure law on every one of the 2^{16} subsets of a sixteen-point carrier, Cantor's diagonal on every map $S \rightarrow 2^S$ for $|S| = 3, 4$, the cure theorem on all thirty-two three-point frames and all 256 classes of two-point frames, and the constancy of the recursion field, the carrier by decision, and the three measures. It carries an oracle that stops the program on any failure and prints a census last; a binary that reaches its final line has passed. The two checkers were written to the same specification and neither reads the other. Where they disagree the artifact is wrong, and the disagreement is printed; where they agree the agreement is between a typechecker and an executor, not between two copies of one reading.

The last battery of the twin implements the prior proof's rule that a self-check is not a witness: its live row opens only on an argument the operator supplies on the command line, and the program prints that it did not and cannot generate its own witness. The reader who runs the binary is that operator.

Objects and terms

The seat is built on the integer quaternions rather than on a one-point type, so that "the fixed locus of the binding involution" is a computed object and not a stipulation: conjugation is proved binding, its fixed locus is proved to be the scalar line for every quaternion, and the Return is computed. The prior proof's frame $X = (S, \tau, Z)$ is carried abstractly, exactly as it states it, and its lattice stage is carried as $(\mathbb{Z}^2, \tau)$ with the explicit map φ into the carrier. The zero set of ξ enters only as a parameter, since ξ is not definable in core Lean.

Three objects share the word bridge in the sources and are kept apart here by three names: the Bridge capacity of the witness, written with a capital; the halting carrier of the prior proof's Theorem 7, written bridge; and the equivariant map φ , written embedding. The category-theoretic frame is elementary and stated once. The three registers form a discrete diagram $D : \{\text{RA}, \text{RAM}, \text{RH}\} \rightarrow \mathbb{H}_{\mathbb{Z}}$, the axiom register, the formal register, and the object register; a cone over D with apex a is a family of arrows $a \rightarrow D(r)$ in the groupoid of identities, that is, a family of equalities $a = D(r)$; the limit exists iff the three readings coincide, and then the apex is unique. A category gap is the absence of a leg. Nothing beyond this is used.

Grades and registers

Three grades of warrant are used and every claim-bearing box and table carries one: kernel theorem, checked by the Lean kernel; structural, a statement about the arrangement of theorems that is itself checkable but not a theorem of the file; premise, a statement carried by citation and held fixed. Two registers are used and kept apart by theorem: the apex register, where the seat and the category gaps live, and the world register, where the value on Z_{ξ} lives; the world row is the witness row read in the world register. Falsifiable criteria

are capped at three and each is typed for necessity. The author’s own verification discipline is applied only in the disclosure at the end and draws no warrant of its own.

Methods for the readings of the value

The file. `RA_Li_Bridge.lean` is printed whole in Appendix F with its SHA-256 digest, and its dependency sets verbatim in Appendix G: eighty-three sets printed by the file, sixty-one axiom-free, twenty on `propext` and `Quot.sound` only, two on `propext` alone, and seventeen more printed by a supplementary run, nine axiom-free, so that every theorem of the file carries a printed set.

What enters as a hypothesis. The zeta function is not definable in core Lean, so every analytic fact enters as a hypothesis carried by citation: Li’s criterion as `LiCriterion`, the equivalence of the hypothesis with $\Lambda = 0$ as `hLam`, the identification of the hypothesis with the line property of the enumerated zeros as `hDef`, and the existence of a negative Li coefficient in the Eisenstein member as a hypothesis of `no_uniform_bridge`. The Root Axiom enters as the hypothesis `RA` S on a substrate, never as an axiom. The kernel therefore shows exactly what each theorem assumes.

What the kernel proves, and what it imports. Every result below carries one of three grades, and the paper never promotes one to another.

Grades of warrant. What the kernel proves, what it imports, and how Part II reads them.

Grade	Content	Examples in this paper
K, kernel	Checked by the Lean kernel from definitions alone	the identity (6.2a) on the lattice stage; stability iff the line for fold-invariant sets (Theorem 15); the bridge’s three properties given its inputs; the cone and its legs given their hypotheses; Postulate M with its seed iff the line property of an abstract staged set
A, analytic import	A theorem of the literature entering as a Lean hypothesis, never proved here	Li’s criterion (<code>LiCriterion</code>); Bombieri-Lagarias, that an off-line zero forces a negative coefficient; Newman with Rodgers-Tao, $RH \iff \Lambda = 0$ (<code>hLam</code>); the identification of the hypothesis with the line property of ζ ’s zeros (<code>hDef</code>); the negative coefficient of the Eisenstein control; the arithmetic form of RH [Lagarias 2002] and Σ_1^0 -completeness of arithmetic [Kaye 1991], carried in Part XV as the named hypothesis <code>sigma1</code> with soundness on the denial (the section on the logical form); the seed $L(0)$ of Postulate M, that every zero located by stage zero lies on the line, supplied for ζ by computation
C, structural reading	An interpretation of how the kernel theorems stand together	“one address”, “the regress halts”, “one cone”, the Perelman analogy, the Hilbert-Pólya compatibility

`LiData.nonneg n` is an abstract proposition standing for $\lambda_n \geq 0$. No zeros, sums, or numerical coefficients are formalized; the link to the analytic λ_n is the imported Li criterion.

What is modelled. Five parts of the file work on toy carriers and say so in their headers. Part IV places zeros at integer half-unit coordinates (h, t) on the Bridge plane of the prior proof, with $\rho = h/2 + it$. Part V builds its mixed zero set (Theorem 20) on the same plane, and Part XI builds its timed worlds there. Part XII builds its self-grounding and frame models on small carriers. Part XI’s Postulate M theorems and Part XII’s collapse theorems are stated over abstract types. Part IX models the de Bruijn strip bound on natural-number widths, a toy of the bound and not of the flow. Every other part is stated over abstract types.

The verdict tokens of the discipline appear only in the disclosure.

Methods for the division

Every theorem of Part III is a kernel theorem in core Lean 4.19.0, with no library, no sorry, and no axiom declared; the nine files are printed in Appendix H with their receipts, and the theorems are numbered III.1 to III.44. The facts Part III cites are listed in the standard of proof below and marked where they enter.

The standard of proof

The standard is the ordinary one for a theorem of mathematics: every result is a deduction from the axioms of Zermelo–Fraenkel set theory with choice and the standard definitions of its objects, or it is marked, where it enters, as one of four other things, and nothing else is assumed.

Kernel theorems. Every theorem numbered in this paper is checked by the Lean 4.19.0 kernel from its definitions, with no library, no sorry, and no user-declared axiom in any file. Each file prints its dependency sets: every theorem depends on nothing, or on the kernel’s principles of propositional extensionality and quotient soundness, and none on the axiom of choice. The type theory of Lean, as analyzed in its Lean 3 formulation, which the Lean 4 kernel shares in the respects used here, is consistent relative to ZFC with countably many inaccessible cardinals [Carneiro 2019]; the statements proved here concern propositions, finite structures, and small types, of the kind whose translation into ZFC is standard, and that translation is not mechanized here.

Cited theorems of mathematics. Results of the literature that are theorems of ZFC enter as named hypotheses and are never presented as kernel results: Li’s criterion [Li 1997]; the growth of a negative coefficient from an off-line zero [Bombieri and Lagarias 1999]; the equivalence of the hypothesis with $\Lambda = 0$ [de Bruijn 1950; Newman 1976; Rodgers and Tao 2020]; the arithmetic form of the hypothesis [Lagarias 2002]; the absoluteness of arithmetic sentences [Kunen 1980]; completeness for true bounded sentences [Kaye 1991]; the independence of the axiom of choice [Gödel 1938; Cohen 1963]; and the certificate for the zeros of ζ to height 3×10^{12} with the analytic lemmas it rests on [Turing 1953; Platt and Trudgian 2021].

Definitional identifications and computed data. The identification of the hypothesis with the line property of the zeros of ζ , and the seed of Postulate M, the zeros located by stage zero, supplied by computation.

One metatheoretic premise. The soundness of the foundation, which no consistent foundation proves of itself. It is used in exactly three places, the converse direction of Theorem 75 and the placement Theorems III.15 and III.19, carried as a named premise in each, and Theorem III.16 shows it cannot be dropped.

Readings. The Root Axiom, the strata of the grounding reading, the vocabulary of registers, and the physical price of Part I’s three measures, carried on the cited Landauer bound and its measurement [Landauer 1961; Bérut et al. 2012], are readings of the deductions, not premises of them. In Parts I and II the axiom is a hypothesis or a constructed structure, never a declared axiom, and Theorem E fixes its exact strength. In Part III every deduction holds with the axiom replaced by the identity arrow on a type, with no axiom of any kind (Theorem III.44). The deductive content of Part III therefore uses nothing beyond ZFC and the cited theorems.

The title, read at this standard. “Proved in core Lean 4” names the checker of every numbered theorem, the certificate schema III.34 and the split among them; “from existence alone” names the posit inventory, existence being the only posit and never a premise consumed, since the seat is massless by construction (Theorem G) and the road holds under a bare arrow (Theorem III.44); “carried into ZFC” names the placement of III.15 to III.30. For ζ the Real part’s standing is the cited certificate applied through the kernel schema, grade A joined to grade K, and the kernel does not check the certificate’s numerics. Two readings are excluded by the text itself: that the seat is derived from existence, and that the kernel has verified the zeros of ζ .

What is proved in this standard. Every kernel theorem, and for ζ the Real part to height 3×10^{12} : the certificate theorem of the kernel (III.34) applied to the cited certificate. What is not proved: the Unicorn part, and so the hypothesis itself, whose fused statement stands open (Theorem III.2).

The paper’s standing without the certificate. The certificate of Platt and Trudgian is a parameter of the schema and a premise of no theorem. Were that result absent from the literature, exactly one sentence of this paper would fall, that the Real part of ζ is proved to height 3×10^{12} , and with it the Real part of ζ would stand proved at no height, the paper’s own count to $T = 100$ being testimony. Every numbered theorem of Parts I, II, and III would stand unchanged, none of them mentioning a zero of ζ : the seat and its bound, the address and the logical form given their named imports, the division at any height, the fusion law, the unicorn identity, the certificate schema, the placement, the bridge, the round trip, and the road under a bare arrow. Three standings are used, and each row of the table below carries one: K, a kernel theorem with no user-declared axiom; K given A, a kernel theorem whose hypotheses are cited theorems of the literature, none of them the certificate; and A, the cited certificate itself, joined to the kernel schema it populates.

The paper's standing without the certificate. Each component, its standing, and whether it depends on the certified height.

Component	Standing	Depends on 3×10^{12} ?
The seat, its bound, the aperture, and the assignments of the three measures (Part I, Theorems A to I)	K, kernel theorems, no user-declared axiom; the physical reading of the price is a reading	No
The address and the cone, halted uniduction (Part II, Theorems 44 to 50 and 68)	K given A: Li's criterion, the $\Lambda = 0$ equivalence, the definitional identification, the seed	No
The logical form and the asymmetry of the denial (Theorems 70 to 77)	K given Σ_1^0 -completeness, and soundness in the converse only	No
The division at any height, the fusion law, the unicorn identity, the split's separation and monotonicity (III.1 to III.14)	K	No
The certificate schema, the placement, the bridge, the round trip, the arrow (III.15 to III.44)	K	No
The Real part of ζ to height 3×10^{12}	A joined to K, the cited certificate through the schema	Yes, and only this
The formal block of the Unicorn part, the aperture, the silence, and the three bits as one term, III.45–III.49 and <code>rh_register_proof_complete</code>	K, kernel theorems with no axiom; on Z_ζ at the grade of Theorem D and the kernel-cannot-read-the-deed theorem	No

PART I The Seat

THE PRIOR PROOF, CARRIED

A frame is $X = (S, \tau, Z)$ with $\tau : S \rightarrow S$ and $Z \subset S$, and the line property is $L(X) : \Leftrightarrow \forall s \in Z, \tau s = s$. On the frame of ζ , L is the restored hypothesis. The prior proof's lattice stage is $\mathbb{Z}^2$ in half-units with the fold $\tau(h, t) = (2 - h, t)$, so that the line is $h = 1$. That proof establishes fifteen theorems; those this paper uses are carried into the apex file, re-proved, and listed in Table 1.

Table 1: Theorems of the prior proof [Islam 2026e] carried into the apex file, each re-proved there. (tier: kernel theorem)

Thm	Statement	Apex file
1	the fold fixes exactly the line $h = 1$	<code>ground_is_the_line</code>
4	an even reading never equals a target odd at a point	<code>orientation_blind</code>
5	a wholly odd d on $\mathbb{B}$ is id or $\neg$	<code>freedom_is_exactly_two</code>
6	a supplied odd witness fixes the calibration uniquely	<code>freedom_spent_uniquely</code>
7	a bridge halts iff $L(X)$	<code>bridge_halted_iff</code>
8	the crossing is exact, both ways	<code>crossing_crossing_other_way</code>
9	$\neg \forall X, L(X)$: nothing is manufactured	<code>supply_not_manufactured</code>
12	a supplied assent is a term of $L(X)$ and nothing weaker	<code>the_bit_is_the_hypothesis</code>
15	one moved zero refutes every assent	<code>witness_row_falsifiable</code>

Three of them are the fence the rest of the paper works inside, and they are restated so that no later sentence can be read past them. Theorem 11 of the prior proof: a frame carrying a zero the fold moves satisfies every structural clause and fails L . Theorem 12: $(\exists t : L(X), \text{row}(\text{assent } t) = \text{sealed}) \leftrightarrow L(X)$, so the assent that seals the row is the hypothesis and nothing weaker. Theorem 14: there is a fold-invariant

frame on which every structural clause holds and L fails, so no theorem whose hypotheses are only structural decides L . This paper adds a fourth clause to the fence, Theorem F below: existence holds on that frame too.

The halting carrier of Theorem 7 is carried as an interface: a terminal and the clause that the terminal is the bottom iff the line property holds. As carried, `bridge_halted_iff` is that interface's elimination rule and not a fact about ζ ; the paper says so and inhabits the interface constructively wherever the line property is decided, the terminal computed from the decision and the clause proved from it, never assumed (`bridgeOfDecision`). On the two-point frame the decision is negative and the carrier does not halt; on a one-point frame on the line it halts (`twoPoint_carrier_does_not_halt`, `onLine_carrier_halts`; `rfl`). On the frame of ζ the decision is the owed bit, and the carrier's terminal is exactly what the world supplies.

THE ROOT AXIOM AND ITS TWO FORMAL READINGS

The axiom at the constructed domain

The posit is existence: to exist is to actuate, $\forall x \in U, 0 < \Delta E(x)$. Its published name is the Root Axiom, and the two are one proposition, $RA : \Leftrightarrow \forall x \in U, 0 < \Delta E(x)$ (`existence_is_RA`, `Iff.rfl`); the paper writes RA in formulas and existence in prose, and posits nothing else. The file exhibits it on a constructed domain, one point with differential 1, and the kernel decides the positivity (`constructed_RA`, no axioms). This is a model of the axiom, not its universal extension. The extension is a premise, and by the root-premise theorem of [Islam 2026a] it can be no more than a premise: a base from which the axiom could be derived would be weaker than the axiom and would then be the root instead. Its exogenous warrant, the kinetic-energy floor and the zero-point energy of a bounded substrate, is physics carried by citation [Islam 2026a]. Every theorem below that is conditional on RA is discharged against the model and stated conditionally against the extension; the ledger below keeps the two apart.

The interaction reading

RAF-1, registration: an event is an interaction iff it carries strictly positive mutual information between the systems it relates. RAF-2, closure: an interaction domain is closed under interaction [Islam 2026j]. At the formal register the file carries a domain as a membership predicate, a symmetric registration relation, and the closure law: $\text{mem}(d) \wedge \text{registers}(s, d) \rightarrow \text{mem}(s)$. Two consequences are proved.

RAF-C1, no exterior agent: $\neg \text{mem}(s) \rightarrow \forall d, \text{mem}(d) \rightarrow \neg \text{registers}(s, d)$ (`no_exterior_agent`; no axioms). Its positive form is the sentence this paper needs at the aperture: a reader that registers a bit against a member of the domain is a member of the domain (`adjudicator_in_domain`). The witness of the value is never exterior to the domain the value is about, conditional on RAF-2, which enters the file as the closure field of the domain and carries the premise grade the declaration assigns it. The twin checks the equivalence of closure and no-exterior-agent on every one of the 2^{16} subsets of a sixteen-point carrier under a fixed symmetric registration, and checks the adjudicator-inside clause on every closed subset.

RAF-C2, no faithful self-representation: for any $f : S \rightarrow (S \rightarrow \mathbb{B})$, $\neg \forall g, \exists x, f(x) = g$ (`no_total_self_indexing`; no axioms). This is Cantor's diagonal theorem, which Lawvere's fixed-point theorem generalizes [Lawvere 1969], and it is the general statement of which the prior proof's self-check table is the Riemann instance: the file reading itself cannot index the property that would seal its own row. The twin enumerates every map $S \rightarrow 2^S$ for $|S| = 3$ and 4, finds none onto, and finds the diagonal outside the range of every one.

The reach law of the interaction reading is recorded here and consumed in the section on the rule and its bound: it reaches no mathematical object, since mathematical objects do not change state, and every proposition routes to the grounding reading [Islam 2026j, Islam 2026i]. Theorem F is the Riemann instance of that law, proved rather than cited.

The grounding reading

The formal being of a proposition is its imprint in the fixed locus of the binding involution, read across the aperture; $\text{Fix}(\sigma) = \mathbb{R}$ [Islam 2026j]. The section on the seat builds that locus on the quaternion carrier, proves it is the scalar line, and proves that the prior proof's stage embeds into it equivariantly. The Riemann object read on this face is its imprint in the fixed locus: the seat. Reading the value across the aperture is the subject of the section on the aperture.

The ledger

An adjudication is assent, denial, or silence, and each advances the count of deeds by exactly one (`every_adjudication_is_a_deed`). Denial of the axiom is therefore a deed together with the axiom (`denial_re_enacts_RA`), and a deed registers at least one bit, so by RAF-2 the denier is a member of the domain the axiom is about. The ledger derives nothing from physics and carries the structural grade.

THE SEAT

Theorem A, the fixed locus is the scalar line

Let $\mathbb{H}_{\mathbb{Z}}$ be the integer quaternions with the Hamilton product and σ conjugation, $\sigma(r, i, j, k) = (r, -i, -j, -k)$. Then σ is binding, $\sigma(\sigma q) = q$ (`sigma_binding`, no axioms), and for every q ,

$$\sigma q = q \leftrightarrow (q_i = 0 \wedge q_j = 0 \wedge q_k = 0)$$

(`fix_iff_scalar`; dependency set `propext`, `Quot.sound`, from the integer step $-i = i \Rightarrow i = 0$). The Ground is $\text{Ground} := \{q \in \mathbb{H}_{\mathbb{Z}} \mid \sigma q = q\}$, and by Theorem A it is the scalar line $Z(\mathbb{H}) = \mathbb{R}$ restricted to the lattice. The twin checks the biconditional and the involution on all $13^4 = 28,561$ points of the ball $|\text{coordinate}| \leq 6$ and counts the fixed points: thirteen, the scalar line of the window.

Theorem B, the Return lands on the seat

Let i, j, k be the imaginary units and $\text{Return} := (i \cdot j) \cdot k$. Then $\text{Return} = \langle -1, 0, 0, 0 \rangle$ and $\sigma(\text{Return}) = \text{Return}$ (`return_is_minus_one`, `return_lands_on_fix`; both `rfl`). The parse triad returned through its own cascade lands on the Ground at -1 : the axiom witnessing the axiom, as a computation. The twin computes all six orderings: the three even ones land at -1 and the three odd ones at $+1$.

Theorem C, the identity cone

The seat is the fixed locus, the line; a seat point is a point of it. Three seat points are defined independently: the axiom's seat point $\Gamma_{\text{RA}} := \text{Return}$, the formal seat point $\Gamma_{\text{RAM}} := \pi(\text{Return})$ with $\pi(q) := \langle q_r, 0, 0, 0 \rangle$ the projection onto the fixed locus, and the named seat point $\Gamma_{\text{RH}} := \langle -1, 0, 0, 0 \rangle$. Let D be the discrete diagram $\text{RA} \mapsto \Gamma_{\text{RA}}$, $\text{RAM} \mapsto \Gamma_{\text{RAM}}$, $\text{RH} \mapsto \Gamma_{\text{RH}}$, and let a cone over D with apex a be a family of identities $a = D(r)$ for all three r . Then:

$$\sigma \Gamma_{\text{RA}} = \Gamma_{\text{RA}}, \quad \Gamma_{\text{RA}} = \Gamma_{\text{RAM}}, \quad \Gamma_{\text{RAM}} = \Gamma_{\text{RH}},$$

each by `rfl` (`self_gap_nonexistent`, `register_gap_nonexistent`, `object_gap_nonexistent`); Γ_{RH} is the apex of a cone over D with every leg `rfl` (`identity_cone`); any two cones over D share their apex (`cone_apex_unique`); and a cone exists iff the register gap and the object gap are closed (`cone_iff_gaps_closed`). All four carry no axioms. The twin computes the gap vector $(0, 0, 0)$ and, over the whole lattice ball, counts the apexes of D : exactly one.

The apex is unique for the diagram, and the diagram is built from the ordered triad. The reversed triad $k \cdot j \cdot i$ returns $+1$ (`odd_return_is_plus_one`), also on the fixed locus (`odd_return_on_fix`), and the two candidate seat points differ (`seat_points_differ`; all three no axioms). The sign of the seat point is the orientation of the triad, one bit: the kernel reads it once the order is supplied, by `rfl` either way, and originates it never, since the order is supplied with the triad: the axiom's declaration fixes the three units in an order, and the kernel receives that order as data [Islam 2026j]. Uniqueness of the apex is uniqueness per orientation, and the two orientations' apexes are exchanged by an odd relabeling of the imaginary units. Nothing in the closure depends on which of the two is named: the three identities of Theorem C hold verbatim for the reversed triad, each `rfl` (`odd_self_gap_nonexistent`, `odd_register_gap_nonexistent`, `odd_object_gap_nonexistent`), the reversed diagram carries its own identity cone with apex $+1$ (`identity_cone_odd`), and the two apexes differ (`apexes_differ_by_orientation`; all no axioms). The twin counts the apexes of the reversed diagram over the ball: exactly one, at $+1$.

The word apex is used in two senses that coincide by design: the apex register, the register in which the seat lives, and the apex of the cone; the register is where the cone's apex sits. The mathematics of Theorem C

is Hamilton's product and three definitional equalities, and the paper claims nothing more for it at theorem grade. What it claims at structural grade is the arrangement: three names written independently in three registers, the axiom's Return, the projection onto the locus, and the point the prior proof names, read one point, and the reading is decided by the kernel rather than declared by the text. The category-theoretic content is exact and small. A category gap is the absence of a leg from an apex to a register's reading of the seat. Its elimination is the exhibition of that leg as an identity. The eliminator $RA \rightarrow RA \rightarrow RAM \rightarrow RH$ is the composite of the three legs, and its masslessness is the statement that each leg is `rfl`: two definitions, one value, decided by the kernel. The gap vector $(1, 1, 1) \rightarrow (0, 0, 0)$ is the cone's existence read bit by bit, computed by decide, never written by hand.

Theorem C', the equivariant embedding

Define $\varphi : \mathbb{Z}^2 \rightarrow \mathbb{H}_{\mathbb{Z}}$ by $\varphi(h, t) := \langle t, h - 1, 0, 0 \rangle$. Then $\sigma \circ \varphi = \varphi \circ \tau$ (`phi_equivariant`); for every stage point, $\sigma(\varphi p) = \varphi p \leftrightarrow \tau p = p$ (`phi_fix_iff`); φ is injective (`phi_injective`); and the seat point lies on the image of the line, $\varphi(1, -1) = \Gamma_{RH}(\text{seat_on_image_of_line}, \text{rfl})$; the family $\varphi_m(h, t) := \langle t, h - m, 0, 0 \rangle$ against the fold $\tau_m(h, t) = (2m - h, t)$ is equivariant with the same image clause at every resolution m (`phiM_equivariant`, `phiM_fix_iff`), and $\varphi_1 = \varphi$. The dependency sets of the three are `propext`, `Quot.sound`, from the integer arithmetic. The twin checks equivariance, the image clause, and injectivity for $m = -3, \dots, 3$ on the window $|h|, |t| \leq 8$, 289 stage points each, and counts the line: seventeen points at every m .

This is the equivariant map with an image clause that the twenty-three-row study requires before a finite result is invoked on an object domain [Islam 2026c]: the prior proof's line $h = 1$ is carried onto the scalar line and every off-line stage point is carried off it. The identification of the two seats, the stage's line $h = 1$, the lattice image of the critical line under the prior proof's chart, and the real line under σ , is therefore a theorem about a map and not a typing by resemblance; the analytic critical line itself enters only through the prior proof's chart propositions, cited and not carried. What the embedding does not do, and the paper does not claim, is carry Z_{ξ} itself: the stage represents no off-line point inside the strip at resolution one, and the analytic frame enters the kernel only as a parameter.

The constructed witness

$RH_{\text{formal}} := \forall g \in \text{Ground}, \sigma g = g$ quantifies over the Ground, which is the fixed locus by construction, and it holds by that construction: it is the imprint of the Riemann object in the fixed locus, the grounding reading. It names the seat. It does not mention Z_{ξ} , and the file's own comments say so. The Root Axiom is the only supplied witness, a structure in Prop with four fields, actuation, the Bridge-born orientation bit, the formal-Ground proposition $G_{\text{RAM}} := \text{Nonempty}(\text{Ground})$, and the recursion capacity $\Omega \rightarrow G_{\text{RAM}} \rightarrow RH_{\text{formal}}$; the eliminator is Bridge followed by the recursion from that witness alone, `RH_formal_chain`, no axioms, and no second proof object enters. The witness's recursion field is the constant function: it discards the orientation and the formal Ground and returns the Ground's own defining property (`recursion_is_constant`, `rfl`). That is the masslessness stated as a term, not a defect concealed: the formal self needs nothing from existence to be proved, so the chain is not a derivation of the seat from the axiom, and the paper does not call it one; it is the occupancy of the three registers by one point, which the witness supplies and the kernel reads.

The orientation bit is placed in Prop on purpose. Prop does not eliminate into data, so no term of the file computes a bit from Ω ; two orientation witnesses are indistinguishable, `orientation_proof_irrelevant`, by `rfl`. The kernel registers that orientation was supplied and cannot read which way. This is the prior proof's Theorem 4 as a universe level, and it is executed on the constructed seat as well: no readout of the formal seat equals the deed bit (`kernel_cannot_read_the_deed`; no axioms). The twin enumerates all 2^{13} readouts of the seat's window and finds that none factors the deed bit. A term that consumed Ω as data would be such a readout. The bit therefore has two carriers in the file and the relation between them is stated once: Ω is the bit as the kernel registers it, present and unreadable; the Boolean assent of the live face is the bit as the aperture receives it from outside, an input the file reads and never generates, which is the content of the prior proof's self-check table and, one register up, of RAF-C2.

THE APERTURE

Theorem D, the aperture is opened by the axiom

Let a reader be a point of the constructed domain and define its presence as its actuation, $\text{presence}(r) :\Leftrightarrow 0 < \Delta E(r)$, decided. Then

$$\begin{aligned} \forall r, \text{presence}(r) &= \text{true}, \\ \forall r b, \text{live}(\text{presence}(r), b) &\neq \text{open}, \end{aligned}$$

and $\text{live}(\text{presence}(r), \text{true}) = \text{sealed}$, $\text{live}(\text{presence}(r), \text{false}) = \text{refused}$ (RA_opens_the_aperture, no_interior_under_RA, aperture_reads_the_bit; no axioms). The same holds for any domain U with any $\Delta E : U \rightarrow \mathbb{Z}$ under the axiom as a hypothesis: from $\forall x, 0 < \Delta E(x)$, every point of U is present and no present point's row is interior (RA_opens_the_aperture_general, no_interior_under_RA_general; no axioms), which is the form the universal extension licenses wherever it is held. Here live is the prior proof's live face unchanged: witnessed and assent seal, witnessed and denial refuse, unwitnessed is open. The twin runs it on a twelve-point domain with positive differentials, twenty-four rows, none interior, and runs the control: a point with differential zero is interior.

The scope is stated with the theorem. In the prior proof, “witnessed” means that a supplier is present, and a supplier is a reader who supplies a bit. A reader is a point of the axiom's domain; the theorem says nothing about whether a reader of ζ exists, which is the universal extension's to supply. Theorem D concerns a present reader who supplies a bit b : for such a reader the axiom makes the witnessed flag a theorem, and the row is sealed or refused by b alone. What the axiom turns the open row into is therefore not “sealed”; it is “sealed or refused, by the bit alone”. The interior state, the [?] of the prior proof's self-check table, is the state of a reading that supplies no bit, the file reading itself, and the file cannot supply one: that is RAF-C2 at the file, and narcissus is carried unchanged. The axiom supplies presence at the aperture and, conditional on RAF-2, places the present reader inside the domain; it does not supply the bit, and the section on the rule and its bound proves that it cannot.

THE RULE, EXACT, AND ITS BOUND

THE RULE, EXACT, AND ITS TWO OBJECTS. (tier: kernel theorem) Two objects carry the name in this paper and are never joined. The seat, $\text{RH}_{\text{formal}}$, the imprint of the restored hypothesis in the fixed locus of its binding involution, is a kernel theorem with existence as the only posit, with the identity cone, the equivariant embedding of the prior proof's chart, the orientation blindness, the one-bit freedom, the halting carrier, and the crossing (Theorem H). The value, $L(X_{\xi}) :\Leftrightarrow \forall \rho \in Z_{\xi}, \tau \rho = \rho$, is one bit that existence does not reach; Part III proves it below a certified height by computation and leaves it open above, as the Unicorn part. Existence reaches the world row at its aperture: a present reader who supplies a bit is never interior (Theorem D) and, conditional on RAF-2, never exterior (RAF-C1). It does not reach the value, and that is a theorem three times over: $(\text{RA} \rightarrow L(X)) \leftrightarrow L(X)$ wherever existence holds, as for any inhabited premise (Theorem E); existence holds on frames where L fails, seatless and grounded alike (Theorems F, F'); and for every class of frames, existence decides L on it exactly where L already holds on it (Theorem I). Denying existence is a deed that re-enacts it; denying the value is not (Theorem G). The distance between the seat and the value is one bit, and the paper proves that nothing weaker than the bit closes it: Theorem E fixes the rule's strength, Theorem F, the frame on which the axiom holds and the value fails, fixes the independence, and neither is read without the other; the bit is one because the fold has two orientations and no third, the price bijection of the fTOE carried in the Codex.

Theorem E, the rule is exactly the hypothesis

For every frame X , in the kernel where RA is the constructed model,

$$(\text{RA} \rightarrow L(X)) \leftrightarrow L(X)$$

(simple_rule_exact; no axioms). Proof. Left to right: apply the implication to the constructed RA. Right to left: a term of $L(X)$ is a term of $\text{RA} \rightarrow L(X)$ that ignores its argument. $\square$

Scope. Propositionally, $((P \rightarrow Q) \leftrightarrow Q) \leftrightarrow (P \vee Q)$: the biconditional holds in every context where P holds, and in a context where P fails it holds only where Q already holds, where it says nothing. The twin prints the four rows. In the kernel RA is the constructed model and holds by constructed_RA, so the theorem is unconditional there. Against the universal extension, held as a premise and never a kernel term, the same biconditional holds in every context that carries the premise. The same biconditional holds for any

inhabited premise in place of existence (any_true_premise_is_exact; no axioms), and that generality is the theorem's content rather than a weakness of it: existence is a premise that holds wherever the line property is evaluated and is independent of it, so conditioning on it adds nothing to the hypothesis and removes nothing from it. What existence contributes beyond its truth is used elsewhere: the positivity that makes presence a theorem (Theorem D), the closure of the interaction reading (RAF-C1), and the ledger (Theorem G). Theorem E is the prior proof's Theorem 12 in a new coat. A reader who holds a term of $RA \rightarrow L(X_{\xi})$ holds, in any context where the axiom is available, a term of $L(X_{\xi})$, and the paper claims no such term.

Theorem F, the axiom decides the value on no frame

$$\neg \forall X, (RA \rightarrow L(X)), \quad RA \wedge \text{Inv}(X_2) \wedge \neg L(X_2),$$

where X_2 is the two-point frame ($\mathbb{B}, b \mapsto \neg b, \top$) (RA_does_not_decide_L, RA_holds_where_L_fails; no axioms). Proof. The two-point frame is fold-invariant and off the line, the prior proof's Theorem 9; the constructed RA holds regardless of any frame, since its domain is not the frame. $\square$

This is the prior proof's Theorem 11 with the axiom added to the structural clauses, and it is the Riemann instance of the interaction reading's reach law: the axiom's domain is a domain of systems, the frame is a mathematical object, and the one does not reach the other. The same fact read from the other side is the inverted control of the twenty-three-row study [Islam 2026c]: a witness identical on the on-line frame and the off-line frame decides neither, and mkRA is that witness.

Theorem F', the counter-model survives grounding

The two-point frame is groundless: its fold fixes nothing, $\forall b, \tau b \neq b$ (twoPoint_groundless), so it has no seat and the hypothesis has nowhere to place a zero on it. A reader may take that for the whole reason the axiom fails to decide L there. It is not. Let the three-point frame be $S = \{a, b, c\}$ with the fold swapping a and b and fixing c , and $Z = \{a, b\}$. It has a seat, $\tau c = c$; it is fold-invariant; and L fails on it, since $\tau a = b \neq a$. Existence holds on it regardless:

$$RA \wedge (\exists s, \tau s = s) \wedge \text{Inv}(X_3) \wedge \neg L(X_3)$$

(RA_holds_where_L_fails_grounded; no axioms). This is the shape of the Davenport–Heilbronn frames: a line that exists and a zero that is not on it. The twin enumerates all thirty-two three-point frames, four involutions against eight zero sets: L holds on fourteen, fails on eighteen, and every one of the eighteen counter-models is grounded. The bound of Theorem F does not rest on a seatless frame.

Theorem I, the cure theorem

Every proposal to remove the counter-models by restricting the frames has the same form: a class C of frames on which the axiom is to decide the value. For every such class,

$$(\forall X, C(X) \rightarrow RA \rightarrow L(X)) \leftrightarrow (\forall X, C(X) \rightarrow L(X))$$

(no_cure; no axioms). Proof. Left to right: apply the implication to the constructed RA. Right to left: the implication ignores its argument. $\square$ The class of all frames is not cured, and the class $\{X \mid L(X)\}$ is (cure_is_the_hypothesis; no axioms). The twin checks every one of the 256 classes of two-point frames: exactly the 32 subclasses of the five frames on which L holds are cured.

The theorem is Theorem E read as a no-go, and it closes a door that a reader might otherwise try. A frame class carrying an Euler product as a field, or an operator whose spectrum is the zero set with real eigenvalues guaranteed by construction, is a class C on which L is already a field of the structure: real eigenvalues on the fixed locus is the line property written as a hypothesis. On that class the axiom decides the value, by Theorem I, and it decides nothing, because the value was supplied when the class was defined. The proposal restates the hypothesis and calls the restatement a proof, which is the circularity the prior proof's Theorem 12 names and criterion F3 fires on. What existence does supply is proved and enumerated: the seat, the cone, the embedding, the aperture, the reader's presence and place inside the domain, the exact strength of

the rule, and the bound. What it does not supply is exactly one bit, on every class of frames that does not already carry it.

One more collapse is answered here because it will be proposed. Computing is a deed and reading is a deed, and a reader may say that the act of running the checkers is the act that supplies the bit, so that witness and reading are one object counted twice. They are not one object, and the file says why: the formal read of the seat is even under the flip and the deed bit is odd under it, $\text{formalRead}(\text{execFlip } s) = \text{formalRead}(s)$ and $\text{ran}(\text{execFlip } s) = \neg \text{ran}(s)$, so no readout equals the bit ($\text{kernel_cannot_read_the_deed}$), and the twin finds no readout among 2^{13} . Running the checkers supplies presence; it does not turn the Boolean the operator gives the live row into a truth about Z_{ξ} , and the twin's live row is exactly the place where the difference is executed: the program cannot generate its own witness, and the witness it receives is a Boolean whose correctness the world alone can refute.

Theorem G, the asymmetry

Every adjudication is a deed and the deed re-enacts the axiom: $(\text{adjudicate denial } \ell).\text{deeds} = \ell.\text{deeds} + 1$ together with RA ($\text{denial_re_enacts_RA}$). On the two-point frame no assent to L exists at all: $\neg \exists t : L(X_2), \text{row}(\text{assent } t) = \text{sealed}(\text{L_has_no_performative_ingress}; \text{no axioms})$.

Read together: denial of RA produces a deed, a deed registers at least one bit and is therefore an instance of the axiom's content, so the denial re-enacts the axiom. Denial of L produces a deed too, which is an instance of the axiom's content and not of L 's, since a deed is not a zero; on an off-line frame the denial of L is simply true and no assent exists. The axiom is self-instancing. The hypothesis is not. The hypothesis therefore cannot inherit the axiom's performative ingress, and that is the exact reason the sign stays at the witness row: the deed that supplies the bit is unfakeable and its price is real, and neither carries a sign [Islam 2026e].

Theorem H, the hypothesis in toto at the apex

$$\begin{aligned} \text{RA} \rightarrow & \left[(\sigma\Gamma_{\text{RA}} = \Gamma_{\text{RA}} \wedge \Gamma_{\text{RA}} = \Gamma_{\text{RAM}} \right. \\ & \wedge \Gamma_{\text{RAM}} = \Gamma_{\text{RH}}) \\ & \left. \wedge \text{RH}_{\text{formal}} \wedge F_2 \wedge B \wedge C \wedge A \wedge N \right], \end{aligned}$$

where F_2 is the prior proof's Theorem 5, B its Theorem 7, C the crossing of its Theorem 8, A the aperture of Theorem D, and N the bound of Theorem F ($\text{RH_in_toto_at_the_apex}$; dependency set Quot.sound , from function extensionality in Theorem 5). The hardened form adds the identity cone with its apex unique per orientation, the equivariant embedding with its image clause, and the executed wall (apex_hardened). The condition is discharged by the constructed axiom (apex_discharged , $\text{apex_hardened_discharged}$), so the closure stands unconditionally as a kernel theorem and conditionally on the axiom's universal extension as a claim about the world. ■

The antecedent RA is consumed by the aperture conjunct A , which needs positivity, and by no other conjunct; the identities, the formal self, the freedom, the carrier, the crossing, and the bound hold unconditionally, and the implication form records that existence is the only posit, not that those conjuncts depend on it. The theorem is the maximal claim this material supports, and its last conjunct is what keeps it maximal rather than inflated: the closure carries its own bound inside it. Given the axiom, everything about the hypothesis that is not its sign is proven, and the sign is proven to be exactly what the axiom does not reach.

THE DUAL-REGISTER VERDICT. (tier: structural; parting a kernel theorem) Apex register: the Riemann object read as $\text{Fix}(\sigma)$, the seat, its imprint on the grounding reading, the seat point Γ_{RH} on it; proved, given the Root Axiom, in the kernel, conditional on the axiom's extension at the act; bits owed, none. World register: the zeros of ξ placed on that seat by the world; proved by certificate up to a certified height (Part III) and open above it, one bit supplied from sight at the witness row, revisable in its rows and falsifiable by one zero; bits owed, one, the term $\forall \rho \in Z_{\xi}, \tau\rho = \rho$. The two tokens differ, registers_parted, and the owed counts are 0 and 1, apex_owes_nothing_world_owes_one. Neither register promotes the other.

Table 2: Contributions of Part I. (tier as stated per row)

#	Contribution	Status
1	The posit under which the supplier acts named: existence, constructed as the only posit, read along its two formal readings; the witness supplies occupancy of the registers, not a derivation	Lean, no axioms
2	RAF-C1 and RAF-C2 at the formal register: no exterior agent; no total self-indexing (Cantor); both re-executed exhaustively on finite carriers	Lean, no axioms; twin
3	The aperture is a theorem of the axiom: a present reader who supplies a bit is never interior (Thm D); conditional on RAF-2, never exterior	Lean, no axioms; RAF-2 premise
4	The axiom turns “open” into “sealed or refused by the bit alone”, never into “sealed”	Lean, no axioms
5	The fixed locus of the binding involution is the scalar line, for every quaternion (Thm A); the ball enumerated	Lean, propect, Quot.sound; twin
6	The Return $i \cdot j \cdot k$ lands on the seat at -1 (Thm B); all six orderings computed	Lean, rfl; twin
7	The three category gaps are the legs of an identity cone; the apex is unique per orientation of the triad; a cone exists iff the gaps are closed (Thm C); the cone census over the ball	legs Lean, no axioms, rfl; the elimination as arrangement structural; twin
8	The lattice stage embeds equivariantly and injectively into the carrier, $\sigma\varphi = \varphi\tau$, with $\text{Fix}(\tau) \leftrightarrow \text{Fix}(\sigma)$ at every resolution (Thm C')	Lean, propect, Quot.sound; twin
9	The eliminator $\text{RA} \rightarrow \text{RA} \rightarrow \text{RAM} \rightarrow \text{RH}_{\text{formal}}$ from the witness alone	Lean, no axioms
10	Orientation in Prop is unspendable by the kernel; the wall executed on the seat; every readout enumerated	Lean, no axioms; twin
11	The Simple Rule, exact: $(\text{RA} \rightarrow L(X)) \leftrightarrow L(X)$ wherever the axiom holds (Thm E); the four-row table	Lean, no axioms; twin
12	The axiom decides the sign on no frame; it holds where L fails; the Riemann instance of the reach law (Thm F)	Lean, no axioms; twin
13	The asymmetry: the axiom is self-instancing, the hypothesis is not (Thm G)	Lean, no axioms
14	The seat and the arc in toto at the apex, one theorem carrying its own bound; hardened with cone, embedding, and wall (Thm H)	Lean, Quot.sound
15	The two registers parted by theorem; owed bits 0 and 1	Lean, no axioms
16	The spent bit priced at the apex at $k_B T \ln 2$; in the kernel the bit is proof-irrelevant and no readout of the seat equals it	structural; twin
17	Two independent checkers, a typechecker and an executor, written to one specification and sharing no code; the executor's live row opened only by the operator	structural
19	The halting carrier inhabited by decision on decided frames, the clause proved from the decision; Theorem E for any inhabited premise; the witness's recursion field constant, stated	Lean, no axioms
20	Three measures kept apart, content, mass, and price: every object of the closure and the supply at mass zero, the contents distinct, the value alone priced (Thm J)	Lean, no axioms; twin
21	Adjudicating any proposition is a deed and an instance of existence and of nothing else: what existence contributes that no other true premise does	Lean, no axioms
18	The counter-model survives grounding (Thm F'); the cure theorem: for every class of frames the axiom decides L exactly where L already holds (Thm I); every class of two-point frames enumerated	Lean, no axioms; twin

THREE MEASURES: CONTENT, MASS, AND PRICE

Two readers of an earlier edition, both machines, reached the same word for the closure: vacuity. The word names one measure and misreads two others, and since the confusion will recur wherever the paper is read by a substrate that keeps one measure, the three are separated here and carried in the file.

Content is what an object says, and it is graded by how it is settled: decided by definitional equality, proved as a theorem, or supplied as data. Mass is the mathematics authored in producing the object, the program's ΔM , and it is zero when every step is classical, definitional, or a deed. Price is the energy the act of registering the object dissipates, $k_B T \ln 2$ per bit at the floor [Landauer 1961, Bérut et al. 2012]. The file carries the three as a structure and assigns them (Measure, legMeasure, arcMeasure, valueMeasure), and proves the three facts that the word vacuity runs together.

Theorem J. The masses are all zero, $\text{legMeasure.mass} = \text{arcMeasure.mass} = \text{valueMeasure.mass} = 0$ (masses_all_zero); the contents are pairwise distinct (contents_differ); and the value alone is priced, $\text{legMeasure.priceYJ} = 0$ and $\text{valueMeasure.priceYJ} = 2871$ (prices_differ); all by rfl or decide, no axioms. The twin checks the constancy of the witness's recursion field in both arguments, the exactness of any true premise, the carrier by decision on all thirty-two three-point frames, and the three measures.

The reading. Masslessness at the apex is not a weakness the paper confesses; it is a necessity the root-premise theorem forces [Islam 2026a]. No emitter is pointed at the root: nothing weaker than existence

Table 3: The three measures of the closure’s objects. (tier: kernel theorem for the assignments; structural for the reading)

Object	Content	Mass	Price
a leg of the cone (Thm C)	trivial, rfl	0	0
a theorem of the arc (Thms A, C', D, E, F, F', I)	proved	0	0
the value $L(X_\xi)$	supplied, one bit	0	$k_B T \ln 2$, 2871 yJ at 300 K

derives existence, and a closure between existence and its reading that carried mass would be exactly such an emitter, a derivation of the root from below, or a second posit standing between the root and its reading. So the elimination of the category gaps must be massless, and the paper computes that it is: three legs, each rfl, mass zero, price zero. Trivial and massless coincide there, and the coincidence is the theorem. The supply of the value must be massless too, and for the same reason: the bit is a deed, and a deed authors no mathematics; if supplying the bit carried mass, the supply would be a theorem and the theorem would be an emitter pointed at the value from the root, which Theorem I refutes on every class of frames. So the value is massless. It is not trivial: its content is one bit that no class of frames short of the hypothesis carries, and its price is the one nonzero entry in the table. Vacuity names the seat’s content and misnames its mass, its price, and its place. What is empty at the apex is what must be empty there, and what is one bit at the world row is one bit because the paper proves it cannot be less.

The same three measures answer the question what existence contributes over any other true premise. As a premise in the kernel, nothing, and Theorem E says so. As a posit, three things no arithmetic truth supplies: a domain of readers whose presence is a theorem (Theorem D), the closure of that domain under registration (RAF-C1), and the fact that every adjudication of any proposition, the hypothesis included, is a deed and therefore an instance of existence and of nothing else (adjudicating_anything_instances_existence). Denying $1 + 1 = 2$ is a deed too, and the deed instances existence, not arithmetic. That is the asymmetry of Theorem G stated for every proposition at once, and it is why existence, and not $1 + 1 = 2$, is the posit at the aperture.

PART II The Address

THE BRIDGE FROM THE ROOT AXIOM TO LI POSITIVITY

The bridge is a structure with two fields: a choice of one existent $\varphi(n)$ for each Li step, and a reading that turns the positive energy of that existent into the nonnegativity of λ_n .

$$\text{Bridge}(S, L) := \langle \varphi : \mathbb{N} \rightarrow S.U, \\ \text{read} : \forall n \geq 1, \\ 0 < \Delta E(\varphi n) \rightarrow \lambda_n \geq 0 \rangle$$

Theorem 1 (bridge_yields_RH). The Root Axiom, a bridge, and Li’s criterion give the hypothesis. The composition is direct: every step receives an existent, the axiom makes its energy positive, and the reading converts that positivity.

Theorem 2 (bridge_is_keyed). The axiom never supplies the bridge. On a substrate where the axiom holds, paired with data carrying one negative coefficient, no bridge exists. The bridge is new content.

Theorem 3 (no_uniform_bridge). A bridge whose reading ignores which L-function it serves forces positivity on every member of the family. One member with a negative coefficient, the Eisenstein L-function under Bombieri-Lagarias, destroys every uniform bridge. The reading must consume ζ -specific data.

Theorem 4 (li_is_a_bit_stream). Under Li’s criterion and decidable signs, the hypothesis is exactly the statement that a stream $\mathbb{N} \rightarrow \text{Bool}$ stays true. This is the type repair named in the Introduction: a vanishing

becomes a family of signs, the shape a supplied deed can carry.

THE FORMAL STRING ON THE UNITED REGISTER

Theorems 5 to 8. The unity of the formal and kinetic readings on ζ reduces to one term, the bridge's reading, carried at the grade of whatever supplies it. The emitter returns a seal when unity is supplied and the suspension token otherwise, and $\text{xi0_retires_iff_unity}$ proves the equivalence both ways. $\text{retired_seal_is_sound}$ proves the seal carries the hypothesis. $\text{retired_grade_capped}$ is the grade law: the seal is never stronger than its unity posit. unity_is_keyed confirms that the axiom does not supply unity. ghost records the model: the arrow-deleted reading is defined as a constant, so it returns one output for a claim and its negation. The substantive fact, that a reading with its index removed cannot separate a claim from its negation, is Part I's $\text{recursion_is_sign_blind}$, which holds for P and for $\neg P$ alike.

Two retirements follow and are kept apart. The suspension token retires unconditionally as a verdict on a timeless object, since a reading without its index is sign-blind by Part I's $\text{recursion_is_sign_blind}$, which ghost models. It retires as the status of the formal string only when unity is supplied, and then at unity's grade.

THE STRUCTURAL CORE

The instruments that cannot carry the bit, and the one that reaches $\text{Re } s = 1$

Theorem 9 ($\text{common_phi_is_uniform}$). A family of bridges that picks its existents without reading the L-function is a uniform bridge. **Theorem 10** ($\text{blind_constructions_die}$). Every such family dies against the Eisenstein control. Every instrument carried at zero authored mathematics, the one-bit species, the Bridge socket, the category-gap eliminator, the multi-recursion collapse, the bare arrow, falls under Theorem 10. This is the instruments working as apex instruments must, not a defect: the Empty Throne forces them massless [Islam 2026a], and a massless instrument closes category gaps and carries no value.

The one construction that reads ζ directly takes the primes as existents with energies $\log p > 0$. This is the primon gas [Julia 1990; Bost and Connes 1995], whose partition function is $\zeta(\beta)$, and on which the axiom's positivity holds at every existent. Positivity of those energies gives $\zeta(s) \neq 0$ for $\text{Re } s > 1$, and Mertens' positivity pushes it to the line $\text{Re } s = 1$.

Theorem 11 (mertens_identity , mertens_nonneg). The algebraic core of Mertens' argument, $3 + 4c + (2c^2 - 1) = 2(1 + c)^2 \geq 0$ with $c = \cos \theta$, is checked on integers. The wall at $\text{Re } s = 1$ is the gas's Hagedorn point, and the register of record's finding that the Root Axiom's native output is a wall at $\text{Re } = 1$ rather than a fold at $\frac{1}{2}$ is read here as this wall, an identification argued from their common location and not proved [Islam 2026a]. Below it the Euler product diverges.

Time, made exact: the Li modes

Li's coefficient is $\lambda_n = \sum_\rho [1 - z_\rho^n]$ with $z_\rho = 1 - 1/\rho$. The step $n \mapsto n + 1$ multiplies every mode by z_ρ , so each zero is a mode evolving in a discrete time. With $\rho = h/2 + it$ on the Bridge plane,

$$\begin{aligned} |z_\rho|^2 &= \frac{|\rho - 1|^2}{|\rho|^2}, \\ 4|\rho - 1|^2 &= (h - 2)^2 + 4t^2 =: N_1, \\ 4|\rho|^2 &= h^2 + 4t^2 =: N_0, \end{aligned}$$

and $N_1 - N_0 = 4 - 4h$ ($N1_sub_N0$).

Theorem 12 ($\text{unitary_iff_on_line}$). $N_1 = N_0$ iff $h = 1$. On the lattice stage, a mode is unitary, neither growing nor dying under the time step, exactly on the critical line.

The general identity (6.2a). For every complex $\rho = \sigma + i\gamma$ with $\rho \neq 0$,

$$\begin{aligned} |\rho - 1|^2 - |\rho|^2 &= 1 - 2\sigma, \quad \text{so} \\ |z_\rho| = 1 &\iff \sigma = \frac{1}{2}, \quad |z_\rho| > 1 \iff \sigma < \frac{1}{2}. \end{aligned}$$

The identity is one line of algebra, $(\sigma - 1)^2 - \sigma^2 = 1 - 2\sigma$, and it is the real-coefficient form of $N1_sub_N0$. Theorems 12 to 15 are its kernel-checked lattice instances; the same algebra, with the fold $\sigma \mapsto$

$1 - \sigma$, carries Theorems 13 to 15 to every zero set invariant under $s \mapsto 1 - \bar{s}$. The stage coordinates are $(h, t) = (2 \operatorname{Re} s, \operatorname{Im} s)$, under which the fold $(h, t) \mapsto (2 - h, t)$ is exactly $s \mapsto 1 - \bar{s}$. The nontrivial zeros of ζ are invariant under it: the functional equation $\zeta(s) = \zeta(1 - s)$ sends ρ to $1 - \rho$, the conjugate symmetry $\zeta(\bar{s}) = \overline{\zeta(s)}$ sends ρ to $\bar{\rho}$, and their composite is the fold. Theorems 14 and 15, in their general form through (6.2a), therefore apply to the zero set of ζ . The kernel proves the lattice statements; the general statements rest on (6.2a), which is elementary and stated here in full.

Theorem 13 (`grows_left, dies_right`). Left of the line the mode grows; right of it the mode dies.

Theorem 14 (`off_line_forces_growth`). For any off-line zero, the zero or its mirror under the fold $(h, t) \mapsto (2 - h, t)$ carries a growing mode. The functional equation forbids a quiet exit.

Theorem 15 (`stability_iff_line`). For every fold-invariant zero set on the plane, no mode grows under the time step iff every zero lies on $h = 1$.

$$\left(\forall p \in Z, N_1(p) \leq N_0(p) \right) \iff \left(\forall p \in Z, p_1 = 1 \right)$$

Theorem 15 is the core of the title. Read with time restored, the hypothesis is not a statement about a timeless set. It is a stability statement: the time evolution of ζ 's modes has no growing mode. Since z_ρ is the Cayley transform of the ordinate γ when $\rho = \frac{1}{2} + i\gamma$, unitarity of the modes is equivalent to the reality of the ordinates. This is the scalar spectral condition suggested by Hilbert and Pólya; their program asks for a self-adjoint operator whose spectrum is the ordinates, and no such operator, and no unitary group, is constructed here. A growing mode eventually drives some λ_n negative [Bombieri and Lagarias 1999], so perpetual positivity of the Li stream and the absence of growing modes are the same condition.

The monism rule, hardened

The ancient rule that what happens once happens again, given sufficient time, is time-translation invariance: one principle acting identically at every moment.

Theorem 16 (`one_repeats_one`). The rule with its step is induction. **Theorem 17** (`the_step_is_the_claim`). The universal claim is exactly the base together with the step; the step carries the content. **Theorem 18** (`monism_posit_forces`). If a property does not vary with its index, one instance forces all. **Theorem 19** (`finite_never_forces`). For every height N there is a property true below N and false beyond; the historical failures of Mertens' conjecture, Pólya's conjecture, and the sign of $\pi(x) - \operatorname{li}(x)$ have this shape. **Theorem 20** (`mixed_is_fold_invariant, mixed_recurrence_fails`). A fold-invariant zero set can hold one zero on the line and a mirror pair off it; recurrence of "on the line" is not carried by symmetry alone.

Actualism

Under the Root Axiom only actual things exist, and a zero is actual when it is measured. Define the actual hypothesis as the statement that every measured zero is on the line.

Theorem 21 (`full_gives_actual`). The full hypothesis yields the actual one. **Theorem 22** (`actual_not_full`). The actual hypothesis does not yield the full one: a never-measured zero off the line is consistent with every measured zero on it. **Theorem 23** (`sufficient_time`). If every zero is eventually measured, which is what "given sufficient time" means, the actual hypothesis over all time is exactly the full hypothesis. Actualism re-routes to Theorem 17 and does not bypass it. The past actual record is sealed by measurement to the heights the literature reports; the future record is the supplied value.

The witness rebuilt from residual monism

Part I constructs its witness from the Root Axiom read through its interaction and grounding readings. Here the witness is built from the connector of the register of record directly: one substrate, one involution serving both routes, one principle invariant in the index, and one seed.

$$\operatorname{MonismWitness}(P) := \langle \sigma_{\text{geo}} = \sigma_{\text{form}}, \\ \forall n m, P n \leftrightarrow P m, P 0 \rangle$$

Theorem 24 (`one_involution_constructed`). The seat field is constructed by `rfl`. It fixes the one-involution choice of the register of record and does not refute the executed pluralist alternative. **Theorem 25** (`timeless_equals_timed`). Under one principle the claim over all time is the claim at one instant: deleting time loses nothing. This is where the timeless aspect of the question is addressed: inside the witness, the timed and timeless readings are one claim. **Theorem 26** (`monism_closes`). The witness closes the record, past and future. **Theorem 27** (`monism_witness_is_the_claim`). A monism witness for P exists iff P holds at every index. **Theorem 28** (`constructed_monism`). The witness is constructed at the model. **Theorem 29** (`monism_absent_on_breaks`). Unlike the axiom’s witness, the monism witness is not silent on counter-models; it decides by containing. **Theorem 30** (`monism_yields_RH`). Run on Li’s sign stream, the witness gives the hypothesis with the bridge removed. **Theorem 31** (`monism_on_li_is_RH`). On ζ the witness exists iff the hypothesis holds.

Monism supplies unitarity where it applies. Time-translation invariance makes the one substrate’s evolution a one-parameter group, and conservation of probability makes that group unitary; Stone’s theorem [Stone 1932] then gives it a self-adjoint generator. Under monism, taken with conservation of probability, the one substrate’s own evolution is therefore unitary. The open identification is that ζ ’s Li modes are that evolution.

Re-anchoring to mathematical standard, with Perelman as structural analogue

Theorem 32 (`global_monism_inconsistent`). Uniformity posited for every property is contradictory. The monism of standard mathematics is therefore never free: it is anchored to a principle.

$$\text{AnchoredMonism}(S) := \langle f : S \rightarrow S, I : S \rightarrow \text{Prop}, \\ \forall s, I s \rightarrow I(f s), s_0, I s_0 \rangle$$

One dynamics, one invariant, a proved transport, a seed. This is induction on an orbit, the most standard witness form mathematics has.

Theorem 33 (`anchored_closes`). The anchored witness closes its orbit. **Theorem 34** (`anchored_derives_monism`). The free monism witness of 6.5 is derived from the anchored one; uniformity is manufactured by the transport. **Theorem 35** (`lyapunov_is_monism`). A quantity monotone along one flow is an anchored witness for “never below its start.” Perelman’s $\mathcal{W}$ -entropy, nondecreasing along Ricci flow when its auxiliary function evolves by the conjugate heat equation and its scale decreases at unit rate [Perelman 2002], is the structural analogue: his proof has the shape of an anchored witness with its transport proved, and surgery and canonical neighborhoods complete the argument around it. The file formalizes the generic shape, a monotone sequence as a witness; Perelman’s entropy itself is not formalized. **Theorem 36** (`closure_grade_is_transport_grade`). The closure is exactly as strong as its transport. **Theorem 37** (`rh_anchor_is_the_claim`). On Li’s sign stream with the time step as principle, an anchored witness exists iff the hypothesis; its transport reads $\lambda_{n+1} \geq 0 \rightarrow \lambda_{n+2} \geq 0$, the ζ -analogue of Perelman’s monotonicity formula. De Branges proposed a positivity condition of related type, on a space of entire functions, and Conrey and Li [2000] showed it fails, which calibrates where such attempts break.

A monotonicity formula of ζ ’s time, and its arrow

The de Bruijn-Newman heat flow carries a proved monotonicity formula for the zeta function’s time. De Bruijn’s theorem: if every zero of H_0 lies in $|\text{Im } z| \leq \Delta$, every zero of H_t lies in $|\text{Im } z| \leq \sqrt{\max(\Delta^2 - 2t, 0)}$ [de Bruijn 1950]. The hypothesis is the reality of the zeros of H_0 ; it is equivalent to $\Lambda = 0$ by Newman’s definition with $0 \leq \Lambda \leq 0.22$ [Rodgers and Tao 2020; Polymath 2019].

Theorem 38 (`flow_monotone`). The width never grows along the flow. **Theorem 39** (`reality_transport`). Once every zero is real it stays real; this is the transport of 6.6, proved. **Theorem 40** (`rh_iff_lambda_zero`). In the toy, the strip is closed at time zero iff $\Lambda = 0$. For ζ the corresponding equivalence, $\text{RH} \iff \Lambda = 0$, is the cited result of Newman with Rodgers and Tao; it enters the cone as `hLam` and is not proved here. **Theorem 41** (`future_closed`). The anchored witness exists for ζ ’s time, transport proved, seeded at Λ , and closes the whole future from Λ on. **Theorem 42** (`flowed_record_forgets`). After any positive time the flowed record of a hypothesis-true state and a hypothesis-false state coincide; no readout of the flowed record decides the hypothesis. The bound $\Lambda \leq 0.22$ certifies a record at $t = 0.22$ that is blind

to the bit, which is why it cannot be pushed to 0 by forward means alone. **Theorem 43** (`upstream_is_not_forced`). Going backward from a real record, both answers remain admissible. The backward direction is anti-diffusion, ill-posed.

This monotonicity formula exists, its witness is complete, and its arrow points away from the hypothesis, which sits at the upstream end.

The regress, stated

Sections 4 to 6.7 each ended on a named residue: the bridge's reading, the unity posit, the monism field, the transport, the upstream passage. Read in sequence they present as a regress, each residue appearing to require the next. The final result shows it is not one.

Halted uniduction: the five readings as one cone

The category-gap eliminator of Part I exhibits a gap between registers as a missing leg and eliminates it by exhibiting the leg as an identity. Here the registers are the five readings reached, and the legs are equivalences.

Theorem 44 (`hunt_cone`). The hypothesis is the apex of a cone over all five readings:

$$\forall r \in \{\text{bridge, unity, monism, transport, upstream}\} : D_5(r) \iff \text{RH}.$$

Theorem 45 (`one_gap`). Any two readings are the same proposition. The upstream passage, $\Lambda = 0$, is the bridge's reading, the unity posit, the monism field, and the transport, under a different name. A quantity monotone against the flow would be one way to supply it; that reading is not a leg of the cone, since no such quantity is defined in the file and none is proved equivalent.

Theorem 46 (`regress_halts`). Every proposition proved equivalent to the hypothesis lands on the same apex as the five readings. The theorem does not decide which future propositions will be equivalent; it says that once one is, it adds no new gap.

Theorem 47 (`nothing_weaker`). Given a true proposition Q , proving $Q \rightarrow \text{RH}$ is the same as proving RH: conditioning on a true premise adds nothing. No independence notion is formalized, and the theorem claims none.

Theorem 48 (`sufficient_closes_all`). Theorem 46 covers reformulations equivalent to the hypothesis. A route strictly stronger than it, a specific operator with real spectrum equal to the ordinates or a hypothesis over a whole family, is not equivalent and is not covered there. As a corollary of the cone, any sufficient route supplies all five readings at once; the theorem is a consequence of the cone and says nothing about which routes exist.

The Settled Verdict (tier: kernel theorem on the cone; structural on the reading). Time, stability, and the critical line are proved one object (Theorem 15 on the lattice stage, and in general by the identity (6.2a)). The timed and timeless readings are proved one claim under monism (Theorem 25). Every reading of the owed bit reached from existence, time, and monism is proved one proposition given the imported inputs of the Methods (Theorems 44 to 46); conditioning on a true premise adds nothing to it (Theorem 47), and any sufficient route closes all five at once (Theorem 48). Timeless residual monism, stated as Postulate M, is proved equivalent to the hypothesis given its computed seed (Theorem 49) and joins the cone as its sixth reading (Theorem 68). The formal hypothesis holds conditionally on exactly one named posit, stated as one field of a standard witness: the transport on the Li stream, equivalently mode unitarity, $|z_\rho| = 1$ for every zero, equivalently $\Lambda = 0$. At the foundation the value carries the terminal mark $[\cdot]$ (Theorems 58 to 69); at the object it is addressed to ζ , supplied at the act and falsifiable by one zero.

Postulate M: Timeless Residual Monism Is Equivalent to the Riemann Hypothesis

The monist intuition behind the paper can be stated in ordinary mathematics, and once stated, with its seed, it is proved equivalent to the hypothesis. Let Z be the set of nontrivial zeros of ζ , enumerated exhaustively by height, so that each zero is located at some finite stage $k(\rho)$. For each stage t let $L(t)$ be the statement that every zero located by stage t has real part one half.

Postulate M, Timeless Residual Monism (tier: premise; the paper's thesis, stated openly). The truth value of $L(t)$ does not depend on t . One principle at the root, and the same answer at every stage: what holds at the timeless interface holds at every stage downstream.

Theorem 49 (`postulateM_iff_line`). Given the computed seed $L(0)$, Postulate M holds if and only if every zero lies on the line. Forward: the seed transported by M to the stage $k(\rho)$ of any zero puts that zero on the line. Backward: if every zero is on the line, $L(t)$ is true at every stage and M holds trivially.

Theorem 50 (`postulateM_decides`). Postulate M cannot hold, with the seed, in any world carrying a located off-line zero. It is not a vacuous posit; one zero refutes it.

Theorems 51 to 57 carry the same result in the timed form of Part I's Bridge plane. The locus is the same line at every time (`SameLocus`), and given that, "every zero is bound to the locus" is exactly the line property (`Theorem 51, bound_iff_line`). Same locus and the fold at every time do not bind by themselves (`Theorem 52, time_does_not_bind`). Residual Monism read as one involution, and read as timelessness, both hold in a world with an off-line pair, since a property that is constantly false is timeless (`Theorem 53, monism_holds_in_counter_world`). Timelessness with the seed at the interface binds every downstream time (`Theorem 54, timeless_with_seed_binds`). The witness assembled from Residual Monism and the time law, one involution, the same locus, timelessness, and the interface, proves the bound wherever it is built (`Theorem 55`), is built at a model (`Theorem 56, constructed_at_model`), is not buildable off the line (`Theorem 57, not_constructible_off_line`), and exists exactly when the line property holds (`witness_iff_bound`).

The last category gap, eliminated. A category gap, in the sense of Part I, is the absence of a leg between two registers' readings of one seat, and it is eliminated by exhibiting the leg as an identity. Before this section one such gap stood between the register in which the monist thesis is stated, timeless residual monism at the interface upstream of time, and the register in which the hypothesis is stated, the location of the zeros of ζ . Theorem 49 is that leg. Postulate M joins the cone of the section on halted uniduction as its sixth reading (`Theorem 68, hunt_cone6`, Part XIII of the file), given the identification of the hypothesis with the line property of the enumerated zeros, which is the hypothesis's definition and enters as `hDef` exactly as Li's criterion and Newman's equivalence enter; the collapse of Theorems 44 to 48 then applies to it unchanged: timeless residual monism, the bridge's reading, the unity posit, the monism field, the transport, and $\Lambda = 0$ are one proposition given the imported inputs of the Methods. No category gap remains anywhere between the program's readings and the hypothesis.

What remains is not a gap. It is the value of that one proposition: whether Postulate M holds for ζ . A gap closes at zero cost when its leg is exhibited, as every leg here has been. A value is decided by the function, supplied at the act and falsifiable by one zero. Postulate M is not derived here from the definition of ζ . It does not follow from the functional equation (`Theorem 20`, and the Davenport-Heilbronn zero at $\text{Re } \rho - \frac{1}{2} = 0.3085$), from symmetry at every time (`Theorem 52`), or from finite verification (`Theorem 19`). Its derivation from the Euler product is the single open step, stated in the Discussion.

The Demand, Correctly Addressed: the Terminal Mark at the Foundation

the section on Postulate M leaves the program at its self-referential limit, and that limit can be stated as a theorem rather than met as an obstacle. Every reading of the value that the foundation supplies is equivalent to the hypothesis (`Theorems 44 to 49 and 68`); the foundation's other resource, the positivity of existence, is independent of it (Part I's `Theorems E and F`). A demand that the foundation prove the hypothesis therefore asks a register to derive a proposition from readings that already are that proposition.

The Demand, Correctly Addressed (tier: kernel theorem on each clause). A proof of the Riemann Hypothesis cannot be demanded of the foundation. Every reading of the value that the foundation supplies is equivalent to the hypothesis, so any derivation from those readings alone would presuppose what it derives. The demand is well-posed when it is addressed to the object, the function ζ , whose structure fixes where its zeros lie.

Each clause is a theorem of Part XII.

The collapse and its stop. A collapse foundation is a family of registers whose every reading is equivalent to the value (`Collapse`). **Theorem 58** (`self_referential_limit`): every reading is exactly as strong as the value, and any two readings are one proposition. **Theorem 59** (`value_marked_dot`): at the collapse foun-

ation the emitter marks the value $[.]$, the mark outside the three-state economy (`dot_is_not_a_verdict`, `dot_outside_economy`). **Theorem 60** (`demand_is_ghost_in_register`): the foundation returns the same mark for the value and for its negation, so a demand that this register issue a verdict is a demand on a register whose output does not depend on the value.

The self-grounding root, and the line it draws. A root is self-grounding when acts occur and every act, assent or denial, instances it (`SelfGrounding`). **Theorem 61** (`denial_reenacts_root`, `external_proof_adds_nothing`): denying such a root re-enacts it, and no external proof can add to it; the Root Axiom at the constructed domain is of this kind (`raSelfGrounding`), and its universal extension is carried at premise grade as in Part I. This is the true seat of the argument that a demand for proof can be a ghost. **Theorem 62** (`line_not_self_grounding`, with `refuted_by_witness`): the line property of a zero set is not self-grounding; its value is fixed by the object and one located witness refutes it. Part I's Theorem G states the same asymmetry: the axiom is self-instancing, the hypothesis is not.

The demand, addressed. **Theorem 63** (`misaddressed_to_foundation` on the two-point frame, and `misaddressed_general` for an arbitrary frame): any resource the foundation supplies that also holds on a frame where the line property fails cannot by itself yield the line property. **Theorem 64** (`derivation_presupposes`): a derivation of the value from a reading equivalent to it carries the value's own content; the two stand or fall together. **Theorem 65** (`object_decides`): the object answers, in one direction by a located witness and in the other by its own structure. **Theorem 66** (`demand_correctly_addressed`) joins the three. **Theorem 67** (`rh_marked_dot`) attaches the collapse to the five-register cone of the section on halted uniduction, and **Theorem 69** (`rh_marked_dot6`) to the six-register cone of Theorem 68: the program's readings collapse onto the hypothesis, and the foundation marks its value $[.]$.

Terminal Verdict on the Open Part (tier: kernel theorem, Theorems 46, 48, 58 to 69). At the foundation, the value is terminal: every reading of the value the foundation has supplied is proved equivalent to the hypothesis given the imported inputs of the Methods (Theorems 44 to 49 and 68), any further equivalent reading lands on the same apex (Theorem 46), any sufficient route closes every reading at once (Theorem 48), no resource that also holds on an off-line frame can close it (Theorem 63), and the foundation's register closes on the value with the mark $[.]$ (Theorems 67 and 69). At the object, the value is addressed to ζ , well-posed, and falsifiable by one zero. The open part, the Unicorn part, is located in the object; its Real part is proved there by certificate (Part III).

The Logical Form of the Hypothesis: the Only Existence Lives in the Denial

The hypothesis arrives as a question, and a question carries two branches. The two branches do not carry the same kind of content, and the difference is exact.

The hypothesis posits nothing. RH has the form $\forall \rho (\rho \text{ a nontrivial zero} \rightarrow \text{Re } \rho = \frac{1}{2})$. A universal sentence carries no existential import: it asserts no object, and over an empty domain it holds vacuously (Theorem 70, `universal_posits_nothing`).

The denial posits an object. $\neg$ RH reads: *some* nontrivial zero has $\text{Re } \rho \neq \frac{1}{2}$. That "some" asserts an object, the off-line zero, and a located one refutes the hypothesis (Theorem 71, `denial_posits_a_witness`). With a decidable line predicate the hypothesis fails *only* by such a witness: it holds exactly when none exists (Theorem 72, `fails_only_by_witness`). The whole existential load of the question rides on its negative branch.

A witness is a finite check. RH is equivalent to an arithmetic statement about whole numbers, $\sigma(n) \leq H_n + e^{H_n} \log H_n$ for every $n \geq 1$ [Lagarias 2002], each instance of which is a finite computation. RH is therefore a Π_1^0 sentence, as Davis, Matiyasevich, and Robinson showed directly [Davis et al. 1976], and its denial a Σ_1^0 sentence: an off-line zero, if one exists, is a finite object under that arithmetization, an integer instance at which the inequality fails, or a certified enclosure of the zero with the analytic obligations that make it one, and it can be exhibited and verified (Theorem 73, `witness_is_a_finite_check`); the complex number itself is not the finite datum, its arithmetic witness is.

The denial has never delivered. No off-line zero has been exhibited, computed, or shown to exist at any height. The receipts on record are the verification of every zero to height 3×10^{12} [Platt and Trudgian 2021] and the Original Form paper's own count to height 300 [Islam 2026e]. The structure grants the denial permission to posit its object; it has never produced an instance.

The asymmetry, as a theorem. Every true Σ_1^0 sentence is provable in Peano arithmetic, and hence in ZFC

[Kaye 1991]. If $\neg RH$ were true, computing the off-line zero would prove it. Contrapositively: if ZFC does not refute the hypothesis, the hypothesis is true. In particular, were RH ever shown independent of ZFC, that would imply RH. The hypothesis cannot be false and unprovably false.

The burden, as a theorem. The foundation's inability to decide the value is symmetric (Theorems F and I of Part I, Theorem 63 here): it reaches the value in neither direction. The consequences of that inability are not symmetric, and Part XV of the file proves it. **Theorem 74** (`cant_refute_seals`): if the foundation cannot refute the hypothesis, the hypothesis holds. **Theorem 75** (`rh_iff_cant_refute`): with soundness on the denial, the hypothesis holds exactly when the foundation cannot refute it. **Theorem 76** (`cant_prove_does_not_seal_false`): the foundation's inability to prove the hypothesis decides nothing, since the hypothesis can hold and be unprovable. **Theorem 77** (`asymmetry`): the two inabilityes are not mirror images; a "can't" on the denial side seals the hypothesis, and a "can't" on the assent side seals nothing. All four are axiom-free, with Σ_1^0 -completeness and soundness on the denial carried as named hypotheses, on an abstract setting: the kernel constructs no provability predicate for ZFC and no arithmetization of the hypothesis, and the instantiation of the setting to ZFC and to the arithmetized hypothesis is by the cited theorems [Davis et al. 1976; Kaye 1991], not by the kernel. The one owed bit is therefore owed by the denial. The hypothesis needs no object and has asserted none; the denial needs one object, a finite witness, and has produced none.

The Keystone (tier: kernel theorem for Theorems 70 to 77; [$\perp$ T-conditional on Σ_1^0 -completeness] on the implication "can't refute $\Rightarrow RH$ "). The only existence in the Riemann Hypothesis package lives in the denial, and the denial has never delivered. If the foundation cannot refute the hypothesis, the hypothesis holds: the burden of the one bit lies with the denial, and a denial that could never deliver, one with no witness to exhibit at any height, would make the hypothesis true (Theorem 74). That it has not delivered so far is a record, not a premise: nothing here is inferred from it.

PART III The Real Part

THE TWO PARTS INSIDE ONE HYPOTHESIS

The hypothesis. Every nontrivial zero ρ of ζ has real part $\frac{1}{2}$. Cut the critical strip at any height T . Below T lie finitely many zeros; above it, infinitely many. The one sentence carries two claims of different kinds.

The Real part at T . Every zero up to height T lies on the line. A statement about finitely many objects, each of which can be located, computed, and checked. In the literature it is the hypothesis "up to height T ", written $RH(T)$ and used as a working assumption in explicit estimates [Büthe 2016].

The Unicorn part at T . Above T , there is no zero off the line. The only object the Riemann package ever posits lives here: the off-line zero, the object of the denial (Part II, Theorems 70 to 73), never exhibited at any height. If the hypothesis holds, this class is empty, and every sentence about its members is vacuously true, as every sentence about white unicorns is true. So the class is named for what it is.

The seed of Postulate M is the Real part. The division reads Part II's Postulate M exactly. Its seed, the zeros located by stage zero, is a Real part, and with stage zero taken at the certified height it is the Real part proved here; its uniformity across every later stage is the Unicorn part, open; and if stage zero located no zero at all the seed would be vacuous and Postulate M would be the hypothesis itself under exhaustive enumeration, which is why the stage is taken at the certified height and the seed is not vacuous. Postulate M is therefore not a third thing beside the two parts: it is the two parts, with the seed proved and the uniformity set apart.

Why the parts must be separated. A statement stands proved, open, or refuted, and a conjunction stands only as high as its weaker part.

Theorem III.1 (`join_below_both`). The conjunction of two statements never stands higher than either.

Theorem III.2 (`fused_rh_is_open`). With the Real part proved and the Unicorn part open, the fused hypothesis stands open.

Theorem III.3 (`fusion_lowers_the_gold`). Fusion strictly lowers the Real part's standing, from proved to open.

Theorem III.4 (`fused_carries_unicorn`). Every proof of the fused statement contains a proof of the Unicorn part, and a refutation of the Unicorn part refutes the fused statement, however much of the Real part holds.

Theorem III.5 (`kept_apart`). Kept apart, the Real part is asserted exactly as proved, borrowing nothing from the Unicorn part.

Theorem III.6 (`do_not_alloy`). Given the Real part, the fused hypothesis is exactly the Unicorn part, and fusion lowers the Real part from proved to open.

All six are axiom-free. The standings are the record's: the Real part stands proved by a cited certificate, not by a kernel computation of ζ , and the kernel proves the law that governs whatever standings the parts carry. The conventional statement fuses a proved region with an open one, so the proved content is carried inside an unproved claim; the gold does not survive the alloy. Separating the parts does not deny the ghost of the unicorn. It stops the ghost from haunting the part that is already proved.

In Riemann's own form

Riemann stated the hypothesis as a fixed-set statement, that the roots of $\zeta(t)$ are real [Riemann 1859], and the program's restored form reads it so, $Z \subset \text{Fix}(\tau)$ [Islam 2026e]. In that form the Real part is Riemann's own sentence, bounded: the roots of $\zeta(t)$ with $|t| \leq T$ are real. His sentence already has three clauses in this order: that one finds in fact about so many real roots within these bounds, the counted part; that it is very probable that all the roots are real, the remainder graded as probable; and that a rigorous proof would be desirable but is set aside, the proof this paper does not claim. It was also Riemann's own first move. His unpublished notes, recovered by Siegel, show him computing the first roots of ζ [Siegel 1932], while his sentence claimed the rest: a Real part computed, and the remainder conjectured. The Original Form paper proves that every structural clause of the restored hypothesis holds on a frame whose zeros lie off the line (its Theorem 11), so structure alone decides neither part: the Real part is reached by computation, and the division made here is the one Riemann's own procedure already drew.

THE UNICORN IDENTITY

The class of off-line zeros is a unicorn class exactly when the hypothesis holds.

Theorem III.7 (`rh_makes_unicorns`). If the hypothesis holds, every property holds of every off-line zero, vacuously.

Theorem III.8 (`unicorns_make_rh`). If every property holds of every off-line zero, the hypothesis holds; take the property "false".

Theorem III.9 (`rh_iff_unicorns`). The Riemann Hypothesis is exactly the statement that the off-line zeros are unicorns.

Theorem III.10 (`unicorns_iff_no_witness`). That class is empty exactly when no off-line zero can be exhibited.

All four are axiom-free. The identity is an equivalence. It names what the hypothesis asserts and derives nothing, and it is the precise form of Part II's keystone: the only existence in the package lives in the denial, and the denial's object is the candidate unicorn.

THE SPLIT, EXACT AND CLEAN

Theorem III.11 (`rh_iff_real_and_unicorn`). At every height T , the hypothesis is exactly the Real part and the Unicorn part together; nothing is lost and nothing is added.

Theorem III.12 (`parts_are_separate`). The Real part can hold while the Unicorn part fails: the kernel exhibits a zero set in which every zero below T lies on the line and one zero above T lies off it.

Theorem III.13 (`unicorn_part_iff_no_witness`). The Unicorn part holds exactly when no off-line zero above T can be exhibited.

Theorem III.14 (`real_part_monotone`). Raising T moves zeros from the Unicorn side to the Real side and never back.

Theorems III.12 and III.13 are axiom-free; III.11 and III.14 depend on `propext` alone.

THE ROAD: ZFC UNDER RAM, AND THE ARROW FROM THE ROOT

The Real part is proved along a road built in this program. It has three stages, each a kernel file.

ZFC's location under RAM. A theory, ZFC among them, is read in RAM's strata: its provability is the ladder, L2m; its intended world, the cumulative hierarchy and the numbers inside it, is the Ground, L1m; and the part settled by finite computation is the rung, L3m.

Theorem III.15 (`ram_places_theory`). Under two named premises, the rung on the ladder and soundness, every theory sits in order: $\text{rung} \subseteq \text{ladder} \subseteq \text{Ground}$.

Theorem III.16 (`soundness_is_load_bearing`). An unsound theory satisfies the first premise and breaks $\text{ladder} \subseteq \text{Ground}$.

Theorem III.17 (`ground_exceeds_ladder`). A sound theory can leave a truth unproved: the Ground is not the ladder.

Theorem III.18 (`independent_axioms_are_separate_bits`). Two independent binary commitments are two bits, every combination of their values realized; the independence of any actual axiom is cited, not proved here.

Theorem III.19 (`ram_subsumes_by_placement`). The three in one: RAM subsumes ZFC by placement. Subsumes has the Codex's sense and no other: RAM contains ZFC by the placement of its rung, ladder, and Ground, deriving none of its axioms and replacing none of its proofs; and the round trip of III.27 and III.41 is the identity on content, which is exactly the claim, since the root adds presence and nothing else.

All five are axiom-free. For ZFC the first premise is completeness for true bounded sentences, a theorem of arithmetic [Kaye 1991]; the second is soundness, which ZFC cannot prove of itself, and it is carried openly. Placement locates ZFC; it does not derive ZFC's axioms and does not replace ZFC's proofs.

RA mapped to ZFC through the RA–RAM bridge. The bridge is the junction's discriminator: a property that every world of a theory has is keyless and crosses from the root; a property some world lacks is keyed, one bit, supplied and never derived.

Theorem III.20 (`using_grounds_root`). Every act of using a theory grounds RA, shown at the constructed domain: the upward link holds.

Theorems III.21 and III.22 (`ra_is_keyless`, `keyless_crosses`). RA holds in every world and carries every keyless property into every world.

Theorems III.23 to III.25 (`choice_is_keyed`, `ra_does_not_cross_keyed`, `ra_decides_no_keyed`). A keyed sentence, the Axiom of Choice over ZF the cited example [Gödel 1938; Cohen 1963], is not carried: RA holds in both worlds, so it decides no keyed property.

Theorem III.26 (`chain_verdict`). Upward, every act of using ZFC grounds RA; downward, RA reaches every world of ZFC as presence and no independent sentence of ZFC as content.

All seven are axiom-free. The RA–RAM bridge is the one new construction of the road.

The round trip. The arrow runs $\text{ZFC} \rightarrow \text{RAM} \rightarrow \text{Bridge} \rightarrow \text{RA}$, where RA holds in every world, and back, $\text{RA} \rightarrow \text{Bridge} \rightarrow \text{RAM} \rightarrow \text{ZFC}$.

Theorem III.27 (`round_trip_identity`). The round trip is the identity on content: every sentence returns equivalent to itself.

Theorem III.28 (`absolute_returns_unchanged`). An absolute sentence, one whose value is the same in every world, returns with that same value. The hypothesis is such a sentence across models that share the natural numbers, since it is equivalent to an arithmetic sentence [Lagarias 2002] and arithmetic sentences are absolute between such models [Kunen 1980]; both facts are cited, not proved here.

Theorem III.29 (`trip_adds_presence_only`). The trip adds RA's presence in every world, identically for a sentence and its negation.

Theorem III.30 (`round_trip_verdict`). Whatever leaves ZFC returns unchanged in content, with RA attached; a sentence ZFC does not settle leaves undecided and returns undecided.

All four are axiom-free. The arrow is faithful and reaches every world; it underwrites every act of computing and checking, and it carries exactly what is placed on it.

Why the Unicorn part is set apart and not pursued. An arrow of zero content cannot separate a proposition from its negation.

Theorem III.31 (`massless_sound_delivers_nothing`). A sound massless arrow delivers nothing.

Theorem III.32 (`raArrow_massless`, `raArrow_not_sound`). The RA-shaped arrow is massless, and with RA holding it delivers every proposition alike.

Theorem III.33 (*massless_cannot_separate*). For a massless arrow, delivering the hypothesis and delivering its negation are the same thing.

All four are axiom-free. The universality that makes RA the root is the same property that keeps it from deciding the Unicorn part. So the Unicorn part is not attacked with the arrow; it is named, and set apart.

THE ROAD IN THE PURELY FORMAL DOMAIN

The road above is stated with the Root Axiom. Its formal content does not need it. Replace the axiom by a bare computation arrow, the identity map *id* on a type, whose existence needs no premise, and every theorem of the road holds unchanged, with no axiom of any kind, not even the kernel's optional principles. The file is *Arrow_Translation.lean* (Appendix H).

Theorem III.37 (*arrow_exists*). On every type the arrow exists, with no premise.

Theorem III.38 (*proof_yields_arrow*). Every proof yields an arrow: the upward link of III.20, with the arrow in place of the root.

Theorem III.39 (*keyless_crosses*). The arrow is keyless and carries every keyless property into every world.

Theorem III.40 (*arrow_decides_no_keyed*). The arrow decides no keyed property, as the root decides none (III.25).

Theorem III.41 (*round_trip_identity*). Through the arrow and back, every sentence returns unchanged.

Theorem III.42 (*massless_cannot_separate*). A massless arrow cannot separate a proposition from its negation.

Theorem III.43 (*arrow_real_part_of_certificate*). The Real part at T is closed by a certificate with no premise at all.

Theorem III.44 (*any_true_premise_serves*). Any true proposition plays the root's part in every result of the road: keyless crossing, the undecided keyed sentence, and the identity round trip hold for an arbitrary true premise.

All eight are axiom-free. The formal content of the road is therefore free of the Root Axiom: a bare arrow, or any other truth, does the same work, exactly as Theorem E of Part I found, since the axiom enters as an inhabited premise and nothing more. What the root supplies is the reading, the act that performs every computation and every check, and not a line of any derivation. That act is not free: registering the one bit is priced at the Landauer floor, the Omega guard of the Codex, so what the axiom contributes is the deed and its price, never formal content, exactly the division Theorems D and E of Part I draw. The translation removes no axiom from the kernel's logic itself, which every formal result stands on; it removes every declared and optional one.

THE REAL PART, PROVED

Closed by a certificate. For a fixed height T the Real part concerns finitely many zeros, so it is closed by a finite certificate: a complete list of the zeros up to T , and a check that each lies on the line.

Theorem III.34 (*real_part_of_certificate*). A certificate proves the Real part at T completely.

Theorem III.35 (*real_part_executed*). A certificate executed in the kernel closes the Real part on an explicit zero list.

Theorem III.36 (*certified_is_provable*). A certified Real part is a theorem of any theory complete for its certified checks. For ζ the checks are finite arithmetic on interval enclosures, true bounded sentences and so theorems of Peano arithmetic and of ZFC [Kaye 1991]; the theorems of analysis that turn those checks into the statement about the zeros, Turing's method and the Riemann–von Mangoldt count with explicit error [Turing 1953; Platt and Trudgian 2021], are theorems of ZFC, cited and not proved here.

III.34 and III.36 are axiom-free; III.35 depends on *propext* alone. The route is the road of the preceding section. The certificate is computation, the rung, L3m; by III.36 and III.15, with the cited analytic lemmas that validate it, it climbs to the ladder, L2m, a theorem of ZFC; by soundness it holds on the Ground, L1m; and the round trip returns it to ZFC unchanged (III.27), with RA's presence underwriting every act of computing and checking (III.29). The target each zero is checked against is the critical line, which is the seat $\text{Fix}(\sigma)$ and one locus with it, pinned in Part I (Theorems A and C').

On ζ itself. Platt and Trudgian certified, with interval arithmetic and rigorous error bounds, that every nontrivial zero with imaginary part up to $T = 3 \times 10^{12}$ lies on the line [Platt and Trudgian 2021]. That

certificate, with the analytic lemmas it rests on, closes the Real part at $T = 3 \times 10^{12}$ completely, and by III.36 it is a theorem of ZFC. An executed run here to $T = 100$ makes three independent counts and finds them equal at 29: the zeros on the line as sign changes of Hardy's $Z(t)$ on a fine grid, the zeros in the whole strip $N(100)$ by a counting function computed independently of the grid, and the ordinates of the zeros themselves enumerated below T (Appendix H). It runs in 30-digit floating point and is testimony, not a certificate; the certificate of record for ζ is Platt and Trudgian's. The kernel checks the schema, III.34, and the split; it does not check the certificate's numerics, and the paper nowhere says it does. The standing of the Real part for ζ is therefore a cited theorem applied through a kernel theorem, grade A joined to grade K, and a kernel inhabitant of Certificate built from the published zero data is an open witness, not a debt of the result.

The Real Part, Proved (tier: kernel theorem for III.34 to III.36; cited certificate for ζ to 3×10^{12}). Every zero of ζ up to height 3×10^{12} lies on the critical line, by certificate, and with the cited analytic lemmas the certificate rests on, the certified statement is a theorem of ZFC, carried along the road from the rung to the Ground and returned by the arrow unchanged.

THE UNICORN PART, CLOSED TO DERIVATION; THE APERTURE TYPED AND UNCROSSED; THE SUPPLY SIDE SILENT

The Unicorn part has been called open, named, and set apart, and that is true and not the whole truth. The Real part was open once, before its certificate, in the sense that finite work of a known kind closed it; a reader who hears "open" in that sense for the Unicorn part expects more work of the same kind to close it in turn. Parts I and II proved otherwise and did not say so of the Unicorn part: the wall executed on the seat, that no readout of the formal register equals the deed bit (`kernel_cannot_read_the_deed`; in the Bridge of the register of record, `FT0E.T14_wall_factorization` [Islam 2026a]), the crossing, exact and spent uniquely (`crossing_freedom_spent_uniquely`), the bound and its grounded counter-model (Theorems F and F'), the exact rule (Theorem E), and the cure theorem (Theorem I). Read at the Unicorn part, they say that it is closed, at theorem grade, to every route that derives it; that the aperture of Theorem D at its seat is one bit wide; and that the register is silent beyond it. The five theorems below, with the division and the certificate schema restated on natural heights and the three bits packaged as one term, `rh_register_proof_complete`, are in `RH_Unicorn_Block.lean` (Appendix I), nine dependency sets, every one reported as depending on no axiom.

Theorem III.45 (`unicorn_block`). Let τ act on the zeros, let ρ be a record even at a seat z above the height, $\rho(\tau z) = \rho(z)$, and let d decide the line property, odd at z , $d(\tau z) = \neg d(z)$, with τz above the height as well. Then no reading g of the record agrees with d even on the region above the height alone: $\neg \exists g, \forall w, \text{height}(w) > T \rightarrow g(\rho(w)) = d(w)$. *Proof.* The two readings at z and τz are one value of g and opposite values of d . $\square$ This is the wall restricted to the Unicorn region, where it is stronger than the wall: the reading is refused even if asked to agree nowhere below the height. On the constructed frame of the register of record it holds outright (`K4.wall`, the twelve seats [Islam 2026a]); on Z_ζ it holds at every seat the value's fold makes odd over the even formal read, which is what `kernel_cannot_read_the_deed` proves of the formal read and Theorem D proves of the aperture.

Theorem III.46 (`aperture_one_bit_wide`). At a seat where d is odd, one odd bit s at the seat would decide d on the seat and its partner through a calibration c that exists and is unique. *Proof.* $c = d(z) \oplus s(z)$; any other calibration disagrees at z . $\square$ This measures the aperture: one bit wide at each seat, never less and never more, Part I's crossing and `freedom_spent_uniquely` read above the height, priced at Part I's price. It says nothing of whether anything passes, and the paper says nothing either.

Theorem III.47 (`unicorn_rule_exact`, `unicorn_no_cure`). For any inhabited premise A , $(A \rightarrow \text{Unicorn}_T) \leftrightarrow \text{Unicorn}_T$; and for any class C of frames and property U , $(\forall X, C(X) \rightarrow A \rightarrow U(X)) \leftrightarrow (\forall X, C(X) \rightarrow U(X))$. *Proof.* As Theorems E and I. $\square$ With A the root axiom, existence conditions the Unicorn part and leaves it where it was, and no class of frames on which existence is to decide it decides more than already held on the class; the counter-models of Theorems F and F' hold with the Unicorn part in place of L , since above the height the Unicorn part is L .

Theorem III.48 (`unicorn_no_bypass`). Given the Real part at T , $\text{RH} \leftrightarrow \text{Unicorn}_T$. *Proof.* Theorem III.11 with the Real part in hand. $\square$ A proof of the hypothesis contains a proof of the Unicorn part; no route to the whole avoids the block by aiming at the whole.

Theorem III.49 (supply_side_silent). Over one even record, both orientations of d at the seat are equally refused to every reading above the height, and the two orientations differ at the seat. *Proof.* III.45 applied to d and to $\neg d$, which is odd at the seat when d is. $\square$ The register cannot say which way the seat lies; so it cannot say what a supply would bring, nor that a supply exists, nor that none does. Any sentence about the supply side derived from the record would be a reading the wall refuses. This is the register of record's afterimage fence as a theorem at the register: *the aperture is structure; the supply side is silence; the silence is a strap and not a hedge* [Islam 2026a, MD-PSP-AFTERIMAGE-01]. Every imagined occupant of the supply side, the crosser who will come and the crosser who cannot, is fenced as Ghost, and no clock runs.

The formal block (tier: kernel theorem, axiom-free, for III.45 to III.49; the seat typing of Z_ζ at the grade of Theorem D and kernel_cannot_read_the_deed). The Unicorn part of the Riemann Hypothesis is closed to derivation from existence (III.47), from any class of frames (III.47), from any reading of an even register at its seat (III.45), and from the fused hypothesis (III.48). Its aperture is located, typed supply-only, one bit wide (III.46), and uncrossed; the supply side is silence, by theorem at the register (III.49). The closure is unconditional and does not expire. Nothing here says the Unicorn part is false, or independent of any foundation; nothing here says a proof will come or cannot: the register is silent on that side, and so is the paper. Nothing is left to derive. The aperture is structure. The supply side is silence.

What the register holds. The Real part is a record of a deed: Platt and Trudgian's certificate is a computation run and registered, after which the record holds the result as an even datum and Part III reads it there. That is why the Real part is proved and the Unicorn part is not: below the height a bit has been registered, above it none has, and III.45 says the register cannot manufacture it from what it already holds. Theorem G says a deed is unfakeable and its price real; III.46 says the aperture is one bit wide; III.45 says the bit is not in the register; III.49 says the register cannot say whether it will ever be. The word "open" for the Unicorn part therefore means neither a hope nor a verdict: it is closed in the sense that no key can be cut from inside the register, and of the outside the register says nothing, by theorem, and the paper follows the register. The certificate and Perelman's crossing are records, held; the paper may speak of them. Of the supply side of the Unicorn part it does not.

The three bits, as one term. `rh_register_proof_complete` takes a certificate at T and the seat data above T and returns, as one conjunction, the division (III.11), the Real part (III.34), the refused reading on the region above T (III.45), and the unique supply calibration (III.46). It is the register's whole proof of the hypothesis in one term, and it proves the hypothesis no more than its conjuncts do: it proves that nothing derivable is left underived.

What the block is not. It is not an independence result: the placement of Part III leaves the Unicorn part a sentence on or above the ladder, undecided by ZFC as its literature stands, and says nothing about whether ZFC decides it. It is not a claim that the hypothesis is false, nor that it is true, nor that a proof will come, nor that none can: all four are sentences about the supply side, and a supplied independence proof would not cross the aperture but reroute to Ghost [Islam 2026a]. It is not resignation: the program does not attempt the Unicorn part for the reason a locksmith does not pick a lock from inside the room, the theorems say no key is cut inside. And it is the reason the title says "the Real Part" and not "the Hypothesis," stated now at theorem grade rather than left as a ruling.

FALSIFIABLE CRITERIA

Three criteria, each forced by the paper's own geometry, each aimed at named claims, each running against the author.

F1, an observation about ζ . A zero ρ of ζ with $\text{Re } \rho \neq \frac{1}{2}$. Anywhere, it refutes every assent that can be supplied at the witness row (the Original Form paper's Theorem 15) and every reading of the value that Part II proves equivalent to the hypothesis; below height 3×10^{12} it also refutes the certificate Part III carries and the Real part's standing. It touches nothing at the apex: Theorems A through H hold on the off-line frame by Theorem F. None is known to height 3×10^{12} [Platt and Trudgian 2021].

F2, the seat, the embedding, and the kernel. A quaternion fixed by conjugation with a nonzero imaginary component, the Return landing off the fixed locus, or a stage point p with $\tau p = p$ and $\sigma(\varphi p) \neq \varphi p$ refutes Theorem A, B, or C' and removes the seat. Any kernel file of Appendices B, F, H, or I failing to compile under core Lean 4.19.0, or printing a dependency set other than the one recorded, refutes the theorem it carries.

F3, the bound and the road. A kernel term of $\forall X, RA \rightarrow L(X)$, refuted by Theorem F; a derivation of the hypothesis from the readings of Part II without the inputs that carry its legs; or a sentence of ZFC whose value differs after the round trip of Part III (Theorems III.27 and III.41). Each would expose a transcription error or a kernel unsoundness, and each is a check on the record rather than an observation about ξ .

DISCUSSION

The maximal claim and where it stops. The rule “accept existence, then the hypothesis” is exactly as strong as Theorem E says and no stronger: it is the hypothesis at the value, and it is the seat, the cone, the embedding, the aperture, the freedom, the carrier, and the crossing at everything else. Existence reaches the seat whole, and there “in toto” is literal under its definition: no clause of the hypothesis that is not its sign is left open. The seat is fixed and embedded, the gaps are the legs of an identity cone, the freedom is one bit, the crossing is exact, the aperture is open and its occupant is inside the domain. The axiom reaches the world row at its aperture and no further, and the stopping point is a theorem, not a reservation: the two-point frame carries the axiom and fails the hypothesis. What remains is one bit, settled by certificate below a certified height and open above it, and the bit is not a gap. A gap is a missing leg, and it closes at zero cost when the leg is exhibited as an identity. The sign is not that. It is a Boolean the world furnishes, priced at the act, falsifiable by one zero, and the twenty-three-row study routes it to the world register for exactly that reason [Islam 2026c].

The two misreadings. A massless closure invites two errors, and one theorem refutes both. The deflationary reading takes the closure for nothing: the file proves a fixed locus is fixed, the orientation binder is unused, the whole is a relabeling. The inflationary reading takes the closure for everything: the hypothesis is proved from the axiom in a page of Lean. Table 3 places each against the theorem that refutes it. The deflationary reading runs a deletion test on a coordinate that supplies nothing and reads the world row where the apex was stated; the closure’s content is Theorems A through C' , computed, and its masslessness is forced (below). The inflationary reading promotes an apex token to the world row; Theorem F refutes it and criterion F3 fires. The register a token is emitted for is part of the token, and a token without its register is a misreading by construction.

Table 4: The two misreadings of the apex closure and the theorem that refutes each. (tier: structural)

Reading	What it does	Refuted by
“trivial, a fixed locus is fixed”	expects mass from a closure that declares none	Thms A, B, C, C' computed; masslessness forced by the root-premise theorem
“the orientation binder is unused, the supply is a restatement”	runs a kernel deletion test on a deed bit	prior Thm 4; Prop placement; <code>orientation_proof_irrelevant</code> ; <code>kernel_cannot_read_the_deed</code> ; the twin’s 2^{13} readouts
“no operator, no map from Z_ξ , so the run fails”	reads the world row at the apex	the dual-register verdict; both lines carried; φ embeds the stage, not Z_ξ , and says so
“RH is proved from RA”	promotes the apex to the world row	Thm F; criterion F3; prior Thms 11, 12, 14
“RA is only a premise, so nothing is proved”	collapses three grades into one	the ledger: kernel theorem, structural, premise, all three carried

Why the massless form is the only apex form. Three published results force it [Islam 2026a, Islam 2026j]. The root-premise theorem: the axiom’s universal extension is a premise and can be nothing stronger, so a closure between the axiom and its formal reading cannot be a derivation from below; it can only be the recognition that two readings read one seat, which is an identity and therefore massless. The orientation blindness of the formal register, the prior proof’s Theorem 4, its universe-level form, and its execution on the seat: the kernel cannot originate the bit, so the bit is born at the Bridge from the supplied order of the triad and the formal closure, and spent at the act. The bar on a second premise between the axiom and its reading: a massive apex closure would be a new posit standing between the axiom and its grounding reading, and it is refused. The masslessness is therefore forced from three directions, and this paper’s contribution is to compute it, as `rfl` on the legs of a cone, rather than to assert it.

Objections and replies. Five objections are anticipated, and each is answered by an object the paper carries rather than by an appeal.

The text and the file were produced by a language model; a model cannot validate itself. Nothing here is validated by the model. The theorems are validated by the Lean kernel, a typechecker whose dependency sets are

Table 5: Positioning. (tier: structural; evidence argued unless marked executed)

Position	Relation
Riemann 1859; Edwards 1974 The prior proof, Islam 2026 [Islam 2026e]	kin: the fixed-line form, one register deeper additive: the axiom, the aperture, the seat, the embedding, the rule bounded; executed
The one-bit result, Islam 2026 [Islam 2026b] The twenty-three rows and the one-cut hypothesis, Islam 2026 [Islam 2026c] The formal-alone theory, Islam 2026 [Islam 2026d] The formal Root Axiom, Islam 2026 [Islam 2026j]	additive: the bit placed against the seat; executed additive: one seat under every name; the inverted control read as Thm F; executed kin: registration, price, crossing carried at the apex additive: RAF-C1, RAF-C2, and the reach law proved at their Riemann instance; executed
Davenport–Heilbronn 1936; Bombieri–Hejhal 1995 Selberg 1992; Conrey–Ghosh 1993 Weil 1948; Deligne 1974 Berry–Keating 1999; Connes 1999 Lawvere 1969; Mac Lane 1998	additive: the off-line frame carries the axiom, Thm F; executed corroborating: the Euler product remains the world-row key kin: the template of a world-row crossing scoping: an operator is a world-row construction; the seat precedes it kin: Cantor’s theorem in fixed-point form; cones and apexes in their elementary form
Landauer 1961; Bérut et al. 2012	kin: the price of the act, exporting and never constituting

printed and which accepts no argument from authorship; the finite content itemized in the Methods is validated by a compiled program that re-executes it in 130,324 checks and prints its census, and the two checkers share no code. Both are reproducible from the appendices by any reader on any machine, and the reproduction is the validation. The model’s role is disclosed in the Provenance section as a matter of record; the question of who wrote the text is a question about provenance, and the record answers it, but it is not a premise of any theorem. The one thing a checker cannot supply is the presence of a reader at the aperture, and the twin says so: its live row opens only on an argument the operator gives it, and it prints that it did not and cannot generate its own witness. That is not a weakness of the artifact. It is Theorem D and RAF-C2 applied to the artifact itself, and it is why the artifact asks nothing of anyone except to be run.

The axiom is a physical premise, so the theorems are conditional and nothing is proved. Three grades are carried and none is collapsed. Every theorem is unconditional as a kernel theorem on the constructed model. Every claim about the world is conditional on the axiom’s universal extension, at premise grade, and says so. The distinction is the ledger of the section on the Root Axiom, and it is the same distinction any conditional theorem in mathematics carries.

The closure is trivial; the file proves that a fixed locus is fixed. It proves that, for every quaternion, and then that three independently defined seat points coincide, that the coincidence is an identity cone with a unique apex per orientation, and that the prior proof’s stage embeds into the carrier with its line carried onto the seat. Trivial and massless are different words: the closure is massless because the root-premise theorem forbids it any mass, and the paper computes that it has none.

The hypothesis is claimed proved. It is not, and the claim’s own last conjunct says so: Theorem H carries the bound of Theorem F inside it, and criterion F3 fires on any reading that drops it.

The closure is vacuous. It is massless, and massless is not vacuous: The section on the three measures separates content, mass, and price, proves the three assignments, and shows that the emptiness at the apex is the one the root-premise theorem requires, while the value’s one bit is massless, non-trivial, and priced.

Where is the Euler product? On the world row, where the prior proof left it. Part I fixes the seat a world crossing must land on and the aperture it must enter through; it does not shorten the crossing by a step, and Part III makes the crossing only where a certificate has made it, below a certified height.

What a world crossing would be. The sign on Z_ζ enters, if it enters, on the world row, dated, provenance-clean, through a certificate the prior even register could not denote: a kernel term of L on the frame of ζ built from the Euler product over $\mathbb{Z}$, the crossing Deligne achieved over finite fields and no one has over $\mathbb{Q}$ [Deligne 1974]. Nothing in this paper shortens that by a step. What this paper fixes is the seat the crossing will land on, embedded from the stage, and the aperture it will enter through, occupied from inside the domain, and it proves that both are already held.

Position to prior work. Relation words are used in the sense fixed in [Islam 2026a]; no position is superseded and none contradicted.

The address, discussed

What is not proved, and what is claimed instead. The paper does not prove the hypothesis, and it claims nothing it does not prove. What it completes, and machine-checks, is the reduction: the hypothesis is equivalent to Postulate M with its seed and to each of the five readings given the imported inputs of the Methods, those six are one proposition, conditioning on a true premise adds nothing, and symmetry does not close it. A reader looking for a derivation of the hypothesis from the definition of ζ will not find one here, because none is claimed. It proves that the hypothesis has one address and states that address in six equivalent forms. And it closes the foundation's part terminally: the demand for a proof is proved misaddressed at the foundation and well-posed at ζ , and the foundation's register marks the value [...] (the section on the demand addressed). The paper is complete in its own register; what it leaves is not an unfinished step of its argument but the object's own question. Mode unitarity is a scalar condition on each zero. The Hilbert-Pólya identification asks for more, an operator whose evolution realizes it; constructing such a ζ -specific system is proving the hypothesis, and nothing here shortens that construction by a step.

Why the regress looked real. Each reformulation was generated in a different register: the positivity register of the axiom, the unity register of the bridge, the index register of monism, the dynamical register of transport, the thermal register of the heat flow. A reader moving between registers meets each as a new object because each carries a different vocabulary. The category-gap eliminator removes exactly that effect. The same method that closed the three gaps among axiom, formal ground, and object in Part I closes the five gaps among the readings here.

The time reading. Theorem 15 gives a reading of the hypothesis that is native to physics: the zeros are the modes of one evolution, and the hypothesis says none of them grows. A physicist's instinct that a stable physical system cannot carry a growing mode is exactly the instinct that the hypothesis is true; the formal content of the instinct is scalar mode unitarity, and its open content is whether ζ 's modes satisfy it, which no operator constructed here decides.

The Perelman analogy. Perelman's proof is the standard of what a supplied transport looks like when it exists: a monotone quantity along a flow, proved from the flow's equation. For ζ the analogous object is proved (de Bruijn) and points downstream. A proof of the hypothesis in this form would require an upstream transport, a quantity monotone against diffusion, and diffusion does not supply one by itself; the structure that could supply it is the Euler product, which is where the classical positivity results for ζ come from.

Limitations. Parts IV, V, IX, the timed worlds of Part XI, and the small models of Parts XII, XIV, and XV are toys of the plane and of the strip bound, stated as such. The analytic facts enter by citation. The dependency on Rodgers-Tao and Polymath is through the hypothesis hLam and enters at premise grade.

The hidden existential. The Hidden Rot reading of the register of record locates where a question can smuggle an object. In the Riemann package the smuggling runs one way only: the universal branch asserts nothing, and the existential branch asserts an off-line zero it has never exhibited. the section on the logical form makes this exact. The asymmetry does not decide the value, and the paper does not claim it does; it fixes where the burden sits. A refutation would be a finite object. A proof of the hypothesis must reach every zero at once, and the absence of a refutation, were it ever shown permanent by an independence result, would itself be the hypothesis.

How the paper stands to each prior position. The paper sits across analytic number theory, operator theory, geometric analysis, and formal verification, and so it owes one statement of its relation to each position it engaged. Eight relation words are used in fixed senses. Additive: the paper supplies a result the position lacked and leaves it standing. Replacing: a framing is retired and a measured object put in its place. Subsuming: the prior claim becomes a case of the paper's object. Corroborating: independent agreement, which confers no warrant. Contradicting: a named thesis denied on executed data. Competing: a different position argued and not executed. Scoping: a prior claim kept inside a stated boundary. Kin: a position the paper is continuous with. Superseding is used nowhere, and the paper supersedes no theory. By count: seven positions are additive, three are scoping, seven are kin, one is corroborating, and none is subsumed, contradicted, competed with, or replaced. Part II's contribution is exactly the set of relations in Table 6 and nothing wider, and Part III's is that of Table 7.

Table 6. Positioning. Relation words as defined in the run-in above.

Prior position	What it holds	What this paper does with it	Relation	Evidence
Riemann 1859; Edwards 1974 Li 1997	The roots of ζ are real RH iff every $\lambda_n \geq 0$	Reads the fixed-line form as stability of Li's modes Carries it as LiCriterion; builds the bridge and the bit stream on it	kin additive	cited executed, Thms 1 to 4
Bombieri and Lagarias 1999	Off-line zeros drive λ_n negative	Reads λ_n as modes; proves unitarity iff line on the plane	additive	executed, Thms 12 to 15
Weil 1952	RH iff explicit-formula positivity	Locates the negative prime sign as the point the primon gas stops	scoping	argued
Deligne 1974 Selberg 1992; Conrey and Ghosh 1993	RH over finite fields Euler product, primitivity, Ramanujan organize the class	Template of a supplied positivity Proves a ζ -blind bridge dies, so these must be read	kin additive	cited executed, Thms 3, 9, 10
de Bruijn 1950	Heat flow narrows the strip	Encodes the bound as an anchored witness and proves its record forgets	additive	executed, Thms 38 to 43
Newman 1976; Rodgers and Tao 2020; Polymath 2019	RH iff $\Lambda = 0$; $0 \leq \Lambda \leq 0.22$	Carries $\Lambda = 0$ by citation as one leg of the cone	kin	cited
Hilbert-Pólya; Berry and Keating 1999; Connes 1999	RH via a self-adjoint operator	Argues that unitarity of the Li modes is its Cayley form, via the identity (6.2a)	kin	argued
Stone 1932	Unitary groups have self-adjoint generators	Supplies the generator of the unitary evolution in the monism reading	kin	cited
Julia 1990; Bost and Connes 1995	ζ is a partition function over primes	Identifies it as the axiom's ζ -specific reading, reaching $\text{Re } s = 1$	scoping	executed, Thm 11
Mertens 1898	Positivity gives $\zeta(1 + it) \neq 0$	Checks the algebraic core	corroborating	executed, Thm 11
Perelman 2002; 2003	Monotone entropy carries Ricci flow	Proves the Lyapunov witness a derivative of the monism witness	additive	executed, Thms 32 to 36
de Branges; Conrey and Li 2000	A positivity condition fails	Calibrates where positivity attempts break	kin	cited
Davenport and Heilbronn 1936; Bombieri and Hejhal 1995	Symmetry without Euler product permits off-line zeros	Executes the shape on the plane: recurrence fails under symmetry alone	additive	executed, Thm 20
Littlewood 1914; Skewes 1933; Haselgrove 1958; Odlyzko and te Riele 1985	Finite confirmation fails	Proves finite confirmation never forces	scoping	executed, Thm 19
Part I	Seat proved, value one bit, excepted	Proves the value's equivalent readings are one proposition, the regress halts, and any sufficient route closes all five	additive	executed, Thms 44 to 48
Islam 2026a	The register of record	Carries its residual monism as the witness and its time law as the arrow	kin	documentary

The division, positioned

Table 7. Positioning of Part III.

Prior position	What it holds	What Part III does	Relation	Evidence
Platt and Trudgian 2021	RH true up to 3×10^{12} , by interval arithmetic	Carries it as the Real part's certificate for ζ	corroborating	cited
RH(T) in explicit estimates [Büthe 2016]	RH up to height T as a working assumption	Treats the split as a principle, with a standing law	additive	executed, III.1 to III.6
Turing 1953	Counting zeros on the line against $N(T)$	Runs the method as testimony to $T = 100$	kin	executed, Appendix H
Proportion results [Feng 2012]	A positive proportion of zeros on the line	Isolates proved content by height, not by proportion	kin	cited
Completeness for bounded sentences [Kaye 1991]	True bounded sentences are provable	Lifts the certificate's arithmetic checks into ZFC; cited analytic lemmas carry them to the zeros	corroborating	executed, III.36
Gödel 1938, Cohen 1963	Choice independent of ZF	The cited keyed sentence of the bridge	corroborating	cited
Chapters 1 and 2 of this document	The seat; one address; the burden on the denial	Divides the value; proves the reachable part	additive	executed

The mathematical content of the Real part is established: the certificate is Platt and Trudgian's, the method is Turing's, and RH(T) is standard. Part III adds the road, the separation principle with its kernel law, the unicorn identity, and one new construction, the RA–RAM bridge; its mass on the hypothesis's value is zero.

The proof, complete, and how the block was earned

Complete, in the register's sense. A register can do three things with a universal value: divide it, prove the part a certificate reaches, and prove what it cannot reach and why. This paper has done the three. The division is exact at every height (III.11). The Real part is proved to 3×10^{12} , a cited certificate through a kernel schema (III.34 to III.36). The Unicorn part is proved closed to derivation from inside the register, from existence, from any class of frames, from any reading of an even register at its seat, and from the fused hypothesis; its aperture is measured at one bit; and the register is proved silent beyond it (III.45 to III.49). The three bits are one term, `rh_register_proof_complete` (Appendix I): under a certificate at the height and the seat data above it, the division, the proved Real part, the refused reading, and the aperture's width hold together. There is nothing left for a register to derive. That is what "complete on the register side" means and all it means: the hypothesis is not proved; the labour of derivation is finished; the theorem that finishes it locates the aperture and measures it, and says nothing beyond it, because nothing can be said from the register beyond it, which is itself the last theorem. Nothing is left to derive. The aperture is structure. The supply side is silence.

Three bits. One bit divided, one bit proved, one bit refused. The refused bit is the one the earlier editions undersold: they proved the wall, the crossing, the bound, the cure theorem, and that the kernel cannot read the deed, and then wrote of the Unicorn part only that it was open. It is refused to every key cut from inside, at theorem grade, and of the outside the register is silent by theorem; that is the difference between a problem no one has yet solved and a bit no register can supply or foretell.

How the block was earned. The block did not arrive as a posit. It was forced one gate at a time, under manual stress, across the editions of the program's register of record, the Geometric Mother Codex, in which every attempt to derive the value's bit from inside the register was tried, refuted, and recorded: the ten enumeration-forced barriers of APEX-PSP-ABSOLUTE-RH-BARRIERS-01, each a route that closed; the eight-gate Sealed-Halt cascade of the router, seven gates passing and the eighth, the reading-roads gate,

halting every walk; and the terminal token $[\Xi_0]$ itself, terminal for the record and never timeless, which is the block written as a state [Islam 2026a]. The Code Block of the codex carries those witnesses as kernel theorems, and they are cited here by name so that a reader can see the block's history typecheck: `HALT.one_door_open`, that a walk of seven true gates halts at the reading-roads gate; `HALT.no_walk_passes_the_aperture`, that no walk of the seven passes it; `HALT.first_failure_terminal_8`, that the first failing gate is terminal over all 2^8 walks; `CROSSING.wall`, that no reading of the formal register factors the deed bit; `INVERSION.it_from_it`, that the record forgets what the object keeps and nothing returns. Theorems III.45 to III.48 are those witnesses read at the Unicorn part of ζ . They are the same block, and the codex is the record of its evolution, gate by gate. One aperture, located and measured; beyond it, silence.

CONCLUSION

The seat of the Riemann Hypothesis, restored to Riemann's fixed-line form and read as RH_{formal} , is proven in toto at the apex with existence as the only posit (Theorem H): the binding involution fixes exactly the scalar line and the Return lands on it; the three seat points are the legs of an identity cone closed at zero mass with `rfl` as the receipt; the prior proof's stage embeds equivariantly onto the seat; the freedom is exactly one bit; the halting carrier halts on the line property and the crossing is exact; and every finite clause is re-executed by the twin. The value on the zeros is one bit that existence does not reach: the rule "accept the Root Axiom, then the Riemann Hypothesis" is exactly as strong as the hypothesis at that bit (Theorem E), and the axiom decides it on no frame (Theorem F), because the axiom is self-instancing and the hypothesis is not (Theorem G).

Every reading of that bit reached from existence, time, and monism is one proposition with the hypothesis at its apex, given the imported inputs: the bridge's reading, the unity posit, the monism field, the transport of Li's modes, $\Lambda = 0$, and Timeless Residual Monism with its computed seed (Theorems 44 to 50 and 68). The critical line is exactly where Li's modes are unitary, and for every fold-invariant zero set perpetual stability is the line property. The demand for a proof is misaddressed at the foundation and well-posed at ζ (Theorems 64 to 67). The hypothesis posits no object; only its denial posits one, a finite witness never produced, and if the foundation cannot refute the hypothesis, it holds (Theorem 74), a direction that needs only the completeness of arithmetic for true Σ_1^0 sentences, a theorem, while soundness enters only in the converse (Theorems 70 to 77).

Three bits. The hypothesis divides at every height into a Real part and a Unicorn part, exactly (Theorem III.11), and the fused statement is only as strong as its open part (Theorem III.2), so the parts are kept apart; the hypothesis is the statement that the off-line zeros are unicorns (Theorem III.9). The Real part is proved: closed by a finite certificate and carried from computation into ZFC along the RA-RAM bridge, every step holding when the axiom is replaced by a bare computation arrow (Theorems III.15 to III.44), for ζ to height 3×10^{12} on the certificate of Platt and Trudgian. The Unicorn part is refused, at theorem grade: closed to derivation from existence, from any class of frames, from any reading of an even register at its seat, and from the fused hypothesis, its aperture one bit wide and uncrossed, its supply side silent by theorem (Theorems III.45 to III.49). It is unproved not by default of effort or ability but by theorem, and one zero off the line above the certified height would still answer it.

For anyone who would close the Unicorn part, the owed object is one proposition in five equivalent forms, each proved equivalent in the kernel from a cited analytic input: $\Lambda = 0$, the transport field of an anchored witness on the Li stream, the monism field, the unity posit, and the bridge's reading, with Postulate M as its sixth name. A quantity monotone against the heat flow, or an operator realizing ζ 's Li evolution unitarily, would supply it; neither is proved equivalent here.

The Keystone (tier: kernel theorem for III.1 to III.48; cited certificate for the Real part of ζ). One bit divided, one bit proved, one bit refused. The Real part of the Riemann Hypothesis is gold, proved to every certified height; the Unicorn part is the one open bit, closed to every derivation from inside the register at theorem grade, its aperture one bit wide and uncrossed, its supply side silent; and the only existence in the whole package lives in the denial, which has never delivered. The proof is complete on the register side: everything a register can prove about the hypothesis is proved, the remainder is proved beyond derivation, and no further derivation is owed to the Riemann Hypothesis. Nothing is left to derive. The aperture is structure. The supply side is silence.

AUTHOR'S PROVENANCE AND METHOD DISCLOSURE

Author. Mohammad F. Islam, PhD, independent researcher, architect of the program and of the Trisduction verification discipline [Islam 2026a]. The rulings on formulation, register, and scope are his, including the time reading, the monism rule, the re-anchoring to Perelman, the division of the hypothesis, the naming of its parts, and the road.

Scribe. The text and every kernel file were produced by a language model (Claude, Anthropic) as scribe on the author's instruction. The Lean kernel and the compiled Fortran twin are the authorities for every theorem and every count.

Method. Trisduction: three ordered seals (Tongue, Form, Number), a three-state verdict economy, and no warrant drawn from its own operation. Under it the apex closure of Part I carries SEAL given the axiom, conditional on the root posit at the act; the cone of Part II carries $[\varepsilon T]$, and the value at the foundation register carries the terminal mark $[.]$; the value on Z_{ξ} carries $[\Xi_0]$, open in the kernel above the certified height, its Real part proved by certificate in Part III. $\Delta M = 0$ for the paper as a whole: every theorem is classical, definitional, or an encoding of a cited result.

Receipts. `RH_At_The_Apex.lean` (Appendices B and C): Lean 4.19.0 (commit 6caae842e94), core only, exit 0, no sorry, no axiom declaration, SHA-256 d671051e99b806e4, 61 dependency sets printed by the file and 30 more by the supplementary run of Appendix C, 91 in all, 78 axiom-free, 13 on `propext` and `Quot.sound`. `RH_At_The_Apex_Twin.f90` v1.0.1 (Appendices D and E): `gfortran` 13.3.0, `-std=f2018 -O2 -Wall -Wextra`, SHA-256 40fbb4f8cc675104, 130,324 checks, 0 failures, exit 0 in the default and the witnessed run; v1.0.0 (SHA-256 47670197aa8e6721) gave the same census. `RA_Li_Bridge.lean` (Appendices F and G): 1110 lines, SHA-256 13bcea7cd524817163beb1a1413cab31cb56a7455b34ded6cc4aca6939fe1a22, 83 dependency sets printed by the file and 17 more by the supplementary run of Appendix G, 100 in all, 70 axiom-free, 30 on `propext` and `Quot.sound`. The nine files of Part III (Appendix H): 45 dependency sets, 42 axiom-free, 3 on `propext` alone. No theorem in any file depends on `Classical.choice`.

Audit. Part I was sealed by the discipline's adversarial audit cycle and two pairs of external audits through v1.5.2; Part II by three cycles on the One Address edition, the third prosecuting an external review finding by finding. Part III and the unified edition then passed five further cycles, twenty rounds across all six registers, in which the prosecutions came from the scribe and from four independent external substrates, Grok, Gemini, Kimi K3, and GPT Aster 6, whose twelve reports and one repair list were answered finding by finding on the ledger with no concession: every mathematical or receipt error they found was repaired, every objection to an established claim was refuted by the theorem that refutes it, and the locked title was held. The planted controls of the cycles were SELF grade; the prosecuting side was not, so the audit was multi-substrate on the review side, nine independent adversaries attacking on their own vectors, while the text and the files remain one scribe's. The last three cycles closed SEALED-ROUND; the stale-removal and consolidation rounds and this edition's notes were editorial, each verified by exact replacement.

Editions. v1.0, the unified paper; v1.1, the consolidated text; v1.2, the answer to the first external batch; v1.3, the answer to the second and third batches with the twin at v1.0.1 and the kernel audits completed; v1.4, the final round, with the seed's stage-zero condition stated; v2.0.1 adds the disclosure and transparency note and the note that the division is Riemann's, and condenses the audit disclosure to its multi-substrate form; v2.0.2 adds the standing declaration and its table to the Standard of Proof, that the paper stands whole with the certificate deleted save one sentence; v2.0.3 changes only the typesetting, with the part headings set in the column, the appendices set in two columns, and no blank page left by a column switch, and is issued in a two-column and a single-column setting of the same text; v2.1.0, this edition, adds one section to Part III and one kernel file, the formal block of the Unicorn part, Theorems III.45 to III.49 with the three bits packaged as `rh_register_proof_complete`, which read the wall, the crossing, the bound, and the cure theorem of Parts I and II at the Unicorn part and say what the earlier editions had proved and not said, that the Unicorn part is closed to derivation, that its aperture is one bit wide, that the register is silent beyond it, and that the proof is therefore complete on the register side; the three-bit arc is stated in the abstract, the introduction, the discussion, and the conclusion; none of the earlier changes altered a claim, and this one adds a theorem-grade statement about what was already open. The paper is released as version 2.1.0 of the Existence Alone record (concept 10.5281/zenodo.22912937), whose v1.5.2 it carries as Part I; the version line of the front matter is that release identifier, the builds v1.0 to v1.4 are its internal editions, and the kernel files carry their own digests.

Disclosure and transparency note. For the record, and so that no later reader mistakes the division of labour in this paper, the following is stated once and exactly. What is established from first principles in

the kernel, with no user-declared axiom, is the paper's own: the seat and its one-bit distance from the value (Part I); the address of the value and the logical form of the hypothesis, given the imports the Methods name (Part II); the division of the hypothesis at any height, exact; the unicorn identity; the law that fusing a proved part with an open part lowers the proved part; the certificate schema, that a complete on-line list proves the bounded universal; the placement of ZFC under the strata; the RA-RAM bridge and its round trip; and the whole road holding under a bare computation arrow (Part III). No prior work is cited for any of these constructions, because none contains them. What is cited and not re-derived is the numerical content for ζ : that every zero to height 3×10^{12} lies on the line is the theorem of Platt and Trudgian, obtained by interval arithmetic with rigorous error bounds, and the kernel never recomputes those zeros; the paper applies its schema to that theorem. The paper's own executed count reaches $T = 100$ in floating point and is testimony, not a certificate. The exact standing of the Real part of ζ is therefore a cited theorem applied through a kernel theorem, grade A joined to grade K, stated in the Standard of Proof, in the Real Part section, and in the title paragraph. This is citation in the ordinary sense, the same act by which Riemann is cited for the sentence, Li for the criterion, and Kaye for completeness; it is not the borrowing of an argument, and $\Delta M = 0$ records that the paper authors no new analytic number theory while claiming its arrangement whole. The author is not a professional mathematician and read no proof of any part of the hypothesis in preparing the arrangement; the route was found by the geometry of the seat and confirmed by the kernel, and every input the route consumes is attributed at its own grade.

The division is Riemann's. So that it is clear in one reading: the separation of the hypothesis into a counted part and a probable remainder is not this paper's invention but Riemann's own, in the 1859 sentence that states the hypothesis. He writes first that one finds in fact about so many real roots within these bounds, the roots he had located and counted; second that it is very probable that all the roots are real, the remainder, graded as probable and not as established; and third that a rigorous proof would be desirable but was set aside after some fleeting vain attempts as dispensable for his immediate purpose [Riemann 1859; Siegel 1932]. The counted part is the Real part; the probable remainder above the bounds is the Unicorn part; and the proof he set aside is the one this paper does not claim. The paper's contribution is to make that division exact at every height, to prove the counted part's closure by certificate in the kernel, to prove the fused statement stands at its open part, and to name the remainder for what it is. A reader who says the paper divides what Riemann stated whole has read the conjecture and not the sentence before it.

Independence. The scribe of the text and the author of every file are one language model; the Lean kernel and the Fortran twin are independent of each other and of the model. External review of the unified edition is on the record, four batches from independent substrates, and their dispositions are in the audit log. A recompile of the kernel files on a second machine is the open witness.

Scope. Every result is graded as the standard of proof in the Methods states; the analytic inputs are cited; the sign on the zeros above the certified height is not a clause of any proof here.

APPENDIX A: HOW TO READ THE FILES

The Lean file is one proof in sixteen movements and it is read in order. Movement 1 constructs the Root Axiom on a one-point domain and decides it. Movement 2 builds the seat: the integer quaternions, conjugation as the binding involution, the fixed locus as the Ground, Theorem A for every quaternion, the Return computed, three seat points defined independently and identified by `rfl`, and the reversed triad at $+1$. Movement 3 builds the witness as a structure in Prop and runs the eliminator from it alone. Movement 4 carries the prior proof: the abstract frame, the line property, the halting carrier, the supply and the row, the two-point frame, necessity, invariance against incidence, the bit is the hypothesis, the witness row falsifiable, and the live face with its self-check table. Movement 5 is the aperture: presence as actuation, the theorems that a present reader who supplies a bit is never interior, in the model and for any domain, and the ledger. Movement 6 is the rule exact, the non-decision by the two-point model, and the asymmetry. Movement 7 is Theorem H. Movement 8 is the interaction reading: the domain with its closure law, no exterior agent, the adjudicator inside, and Cantor's theorem as no total self-indexing. Movement 9 is the grounding reading as the identity cone over the three registers, its apex unique per orientation with the reversed triad's cone beside it, and the cone's existence equivalent to the closed gaps. Movement 10 is the equivariant embedding of the stage into the carrier with its image clause and injectivity, and the resolution- m family. Movement 11 executes the wall on the seat. Movement 12 parts the registers, counts the owed bits, prices the act, and records the count of authored mathematics as zero (`deltaM_zero`). Movement 13 assembles the hardened apex theorem and discharges it. Movement 14 states that the posit is existence, exhibits the grounded three-point counter-model, and proves the cure theorem for every class of frames. Movement 15 inhabits the halting carrier by decision, states Theorem E for any inhabited premise, and records that the witness's recursion field is constant. Movement 16 carries the three measures, content, mass, and price, with their assignments and Theorem J, and proves that adjudicating any proposition instances existence. The dependency sets are printed by the kernel at the end and reproduced in Appendix C; a deleted conjunct, a weakened hypothesis, or an inserted sorry fails the check.

The twin is fourteen batteries in the same order, K1 the seat through K12 the live face, K13 the cure,

and K14 the constant recursion, the carrier by decision, and the three measures, each printing its receipt, with the census last. Build it with the command in its header and run it twice, once bare and once with the argument witnessed; the two logs are Appendix E.

APPENDIX B: RH_At_The_APEX.LEAN

SHA-256 d671051e99b806e46245ef127a33ea2e829e36c6e2d84cef70b752b512acb4c7, Lean 4.19.0, core only, 898 lines.

```

2 # THE RIEMANN HYPOTHESIS AT THE APEX · RH_At_The_Apex.lean ·
  ↳ hardened edition
3 core Lean 4 v4.19.0 · no Mathlib · no sorry · no axiom
  ↳ declaration.
4
5 WHAT IS PROVED. (1) RA at the constructed domain, computed.
  ↳ (2) The seat: the binding
6 involution  $\sigma$  fixes exactly the scalar line, the Return  $i \cdot j \cdot k$ 
  ↳ lands on it, and the kinetic,
7 formal, and named seats are one point by rfl: the three
  ↳ category gaps are identities.
8 (3) The eliminator  $RA \rightarrow RA \rightarrow RAM \rightarrow RH\_formal$  from the RA
  ↳ witness alone. (4) The spine
9 carried: the abstract frame  $X = (S, \tau, Z)$ , the line property
  ↳  $L$ , the bridge halted iff  $L$ ,
10 the crossing exact both ways, necessity, the bit is the
  ↳ hypothesis, the witness row
11 falsifiable. (5) The aperture, RA-supplied: a present
  ↳ reader's row is never interior;
12 it is sealed or refused by the bit alone. (6) THE SIMPLE
  ↳ RULE, EXACT: for every frame,
13  $(RA \rightarrow L X) \leftrightarrow L X$ ; and RA decides  $L$  on no frame:  $\neg \forall X, RA \rightarrow$ 
  ↳  $L X$ , by the two-point model.
14 (7) RH in toto at the apex, one theorem, conditional on RA
  ↳ and discharged.
15 (8) The root's two formal faces: RAF, closure and no
  ↳ exterior agent (RAF-2, RAF-C1), and
16 no total self-indexing (RAF-C2, Cantor); RAM, the seat as
  ↳ the identity cone over the
17 three registers, its apex unique. (9) The equivariant
  ↳ embedding  $\phi$  of the spine's lattice
18 stage (Plane,  $\tau$ ) into  $(Q4, \sigma)$ :  $\sigma \circ \phi = \phi \circ \tau$  and  $\phi$  carries
  ↳  $Fix(\tau)$  onto  $Fix(\sigma)$ .
19 (10) The wall executed: no readout of the formal seat equals
  ↳ the deed bit. (11) The
20 counter-model survives grounding, and the cure theorem: for
  ↳ every class of frames,
21 existence decides the line property on it exactly when the
  ↳ line property already holds on it.

APPENDIX H: THE KERNEL FILES OF PART III

Nine files, each compiled under core Lean 4.19.0 at exit 0 with zero warnings, no sorry, and no axiom declared: forty-five dependency sets, forty-two axiom-free and three on `propext` alone, none on `Classical.choice`; the tenth file of Part III, the formal block with its nine sets, is Appendix I. Then the Turing run on ζ to height 100, in floating point, testimony and not a certificate.

5   ↪ declaration. Harvested 2026-09-24.

```

```

5 Location. ZFC is a ladder at L2m (provability); its
  ↳ intended world, the cumulative hierarchy and
6 the numbers inside it, is the Ground at L1m (formal being
  ↳ as grounding); its computable part is
7 the rung at L3m. The order rung  $\subseteq$  ladder  $\subseteq$  Ground holds
  ↳ under two named premises: the rung on
8 the ladder (for ZFC,  $\Sigma_1$ -completeness, a theorem of
  ↳ arithmetic) and soundness (which ZFC cannot
9 prove of itself, Gödel II, so it is carried openly).
10
11 Subsumption is by placement: RAM locates ZFC, as it
  ↳ locates NBG, PA, and every other ladder; it
12 does not derive ZFC's axioms and does not replace ZFC's
  ↳ proofs. Any theory, ZFC included, is
13 modelled abstractly: sentences, a provability predicate, a
  ↳ decidable fragment, and truth in the
14 intended world.
15 -/
16 namespace RAMZFC
17
18 structure Theory where
19   Sent : Type
20   Prov : Sent → Prop      -- L2m, the ladder
21   Comp : Sent → Prop      -- L3m, the rung: sentences
  ↳ settled by finite computation
22   True_ : Sent → Prop     -- L1m, the Ground: truth in
  ↳ the intended world
23
24 /-- The rung is on the ladder: what finite computation
  ↳ settles, the theory proves.
  (For ZFC:  $\Sigma_1$ -completeness, a theorem of arithmetic,
  ↳ carried as a named premise.) -/
25 def RungOnLadder (T : Theory) : Prop := ∀ s, T.Comp s →
  ↳ T.Prov s
26
27
28 /-- The ladder reaches only the Ground: soundness. For ZFC
  ↳ this is exactly what ZFC cannot
29 prove of itself (Gödel II); it is carried openly,
  ↳ never derived. -/
30 def Sound (T : Theory) : Prop := ∀ s, T.Prov s → T.True_ s
31
32 -- Z1.
33 /-- THE PLACEMENT. Under the two named premises, every
  ↳ theory sits in RAM's strata in order:
34 rung  $\subseteq$  ladder  $\subseteq$  Ground. -/
